Class "BSParams"

Description

A parameter class for representing all parameters needed for running the `bsapply` method.

Objects from the Class

Objects can be created by calls of the form `new("BSParams", ...)`. 

Slots

- **X**: a BSgenome object that contains chromosomes that you wish to apply `FUN` on
- **FUN**: the function to apply to each chromosome in the BSgenome object ’X’
- **exclude**: this is a character vector with strings that will be used to filter out chromosomes whose names match these strings.
- **simplify**: TRUE/FALSE value to indicate whether or not the function should try to simplify the output for you.
- **maskList**: A named logical vector of maskStates preferred when used with a BSGenome object. When using the bsapply function, the masks will be set to the states in this vector.

Methods

- **bsapply(p)** Performs the function `FUN` using the parameters contained within `BSParams`.

BSgenome-class

The BSgenome class

Description

A container for the complete genome sequence of a given species.

Accessor methods

In the code snippets below, x is a BSgenome object and name is the name of a sequence (character-string).

organism(x): Return the target organism for this genome e.g. "Homo sapiens", "Mus musculus", "Caenorhabditis elegans", etc...

species(x): Return the target species for this genome e.g. "Human", "Mouse", "C. elegans", etc...

provider(x): Return the provider of this genome e.g. "UCSC", "BDGP", "FlyBase", etc...

providerVersion(x): Return the provider-side version of this genome. For example UCSC uses versions "hg18", "hg17", etc... for the different Builds of the Human genome.

releaseDate(x): Return the release date of this genome e.g. "Mar. 2006".

releaseName(x): Return the release name of this genome, which is generally made of the name of the organization who assembled it plus its Build version. For example, UCSC uses "hg18" for the version of the Human genome corresponding to the Build 36.1 from NCBI hence the release name for this genome is "NCBI Build 36.1".

sourceUrl(x): Return the source URL i.e. the permanent URL to the place where the FASTA files used to produce the sequences contained in x can be found (and downloaded).

seqnames(x): Return the index of the single sequences contained in x. Each single sequence is stored in an XString or MaskedXString object and typically comes from a source file (FASTA) with a single record. The names returned by seqnames(x) usually reflect the names of those source files but a common prefix or suffix was eventually removed in order to keep them as short as possible.

seqlengths(x): Return the lengths of the single sequences contained in x.

See `?length,XString-method` and `?length,MaskedXString-method` for the definition of the length of an XString or MaskedXString object. Note that the length of a masked sequence (MaskedXString object) is not affected by the current set of active masks but the nchar method for MaskedXString is.

names(seqlengths(x)) is guaranteed to be identical to seqnames(x).

mseqnames(x): Return the index of the multiple sequences contained in x. Each multiple sequence is stored in an XStringSet object and typically comes from a source file (FASTA) with multiple records. The names returned by mseqnames(x) usually reflect the names of those source files but a common prefix or suffix was eventually removed in order to keep them as short as possible.

names(x): Return the index of all sequences contained in x. This is the same as c(seqnames(x), mseqnames(x)).

length(x): Return the length of x, i.e., the number of all sequences that it contains. This is the same as length(names(x)).
BSgenome-class

x[[name]]: Return sequence (single or multiple) named name. No sequence is actually loaded into memory until this is explicitly requested with a call to x[[name]] or x$name. When loaded, a sequence is kept in a cache. It will be automatically removed from the cache at garbage collection if it’s not in use anymore i.e. if there are no reference to it (other than the reference stored in the cache). With options(verbosTRUE), a message is printed each time a sequence is removed from the cache.

x$name: Same as x[[name]] but name is not evaluated and therefore must be a literal character string or a name (possibly backtick quoted).

masknames(x): The names of the built-in masks that are defined for all the single sequences. There can be up to 4 built-in masks per sequence. These will always be (in this order): (1) the mask of assembly gaps, aka "the AGAPS mask"; (2) the mask of intra-contig ambiguities, aka "the AMB mask"; (3) the mask of repeat regions that were determined by the RepeatMasker software, aka "the RM mask"; (4) the mask of repeat regions that were determined by the Tandem Repeats Finder software (where only repeats with period less than or equal to 12 were kept), aka "the TRF mask". All the single sequences in a given package are guaranteed to have the same collection of built-in masks (same number of masks and in the same order).

masknames(x) gives the names of the masks in this collection. Therefore the value returned by masknames(x) is a character vector made of the first N elements of c("AGAPS", "AMB", "RM", "TRF"), where N depends only on the BSgenome data package being looked at (0 <= N <= 4). The man page for most BSgenome data packages should provide the exact list and permanent URLs of the source data files that were used to extract the built-in masks. For example, if you’ve installed the BSgenome.Hsapiens.UCSC.hg18 package, load it and see the Note section in ‘BSgenome.Hsapiens.UCSC.hg18’.

Examples

## Loading a BSgenome data package doesn’t load its sequences
## into memory:
library(BSgenome.Celegans.UCSC.ce2)

## Number of sequences in this genome:
length(Celegans)

## Display a summary of the sequences:
Celegans

## Index of single sequences:
seqnames(Celegans)

## Lengths (i.e. number of nucleotides) of the sequences:
seqlengths(Celegans)

## Load chromosome I from disk to memory {hence takes some time}
## and keep a reference to it:
chrI <- Celegans[["chrI"]]
# equivalent to Celegans$chrI
chrI

class(chrI)  # a DNAString instance
length(chrI)  # with 15080483 nucleotides

## Multiple sequences:
msgenomes(Celegans)
upstream1000 <- Celegans$upstream1000
upstream1000
class(upstream1000)  # a DNAStringSet instance
## Character vector containing the description lines of the first
## 4 sequences in the original FASTA file:
names(upstream1000)[1:4]

## PASS-BY-ADDRESS SEMANTIC, CACHING AND MEMORY USAGE
## ---------------------------------------------------------------------
## We want a message to be printed each time a sequence is removed
## from the cache:
options(verbose=TRUE)

gc()  # nothing seems to be removed from the cache
rm(chrI, upstream1000)
gc()  # chrI and upstream1000 are removed from the cache (they are
  # not in use anymore)

options(verbose=FALSE)

## Get the current amount of data in memory (in Mb):
mem0 <- gc()"Vcells", "(Mb)"

system.time(chrV <- Celegans[["chrV"]])  # read from disk
gc()"Vcells", "(Mb)" - mem0  # chrV occupies 20Mb in memory

system.time(tmp <- Celegans[["chrV"]])  # much faster! (sequence
  # is in the cache)

gc()"Vcells", "(Mb)" - mem0  # we're still using 20Mb (sequences
  # have a pass-by-address semantic
  # i.e. the sequence data are not
  # duplicated)

## subseq() doesn't copy the sequence data either, hence it is very
## fast and memory efficient (but the returned object will hold a
## reference to chrV):
y <- subseq(chrV, 10, 8000000)
gc()"Vcells", "(Mb)" - mem0

## We must remove all references to chrV before it can be removed from
## the cache (so the 20Mb of memory used by this sequence are freed).
options(verbose=TRUE)
rm(chrV, tmp)
gc()
## Remember that 'y' holds a reference to chrV too:
rm(y)
gc()

options(verbose=FALSE)
gc()[*Vcells", "(Mb)*"] - mem0

### BSgenomeForge

#### The BSgenomeForge functions

**Description**

A set of functions for making a BSgenome data package.

**Usage**

```r
## Top-level BSgenomeForge function:
forgeBSgenomeDataPkg(x, seqs_srcdir=".", masks_srcdir=".", destdir=".", verbose=TRUE)

## Low-level BSgenomeForge functions:
forgeSeqlengthsFile(seqnames, prefix="", suffix=".fa",
                   seqs_srcdir=".", seqs_destdir=".", verbose=TRUE)
forgeSeqFiles(seqnames, mseqnames=NULL, prefix="", suffix=".fa",
              seqs_srcdir=".", seqs_destdir=".", verbose=TRUE)
forgeMasksFiles(seqnames, nmask_per_seq,
                seqs_destdir=".", masks_srcdir=".", masks_destdir=".",
                AGAPSfiles_type="gap", AGAPSfiles_name=NA,
                AGAPSfiles_prefix="", AGAPSfiles_suffix="_gap.txt",
                RMfiles_name=NA, RMfiles_prefix="", RMfiles_suffix=".fa.out",
                TRFfiles_name=NA, TRFfiles_prefix="", TRFfiles_suffix=".bed",
                verbose=TRUE)
```

**Arguments**

- `x`: A BSgenomeDataPkgSeed object or the name of a BSgenome data package seed file. See the BSgenomeForge vignette in this package for more information.
- `seqs_srcdir`, `masks_srcdir`:
  - Single strings indicating the path to the source directories i.e. to the directories containing the source data files. Only read access to these directories is needed. See the BSgenomeForge vignette in this package for more information.
- `destdir`: A single string indicating the path to the directory where the source tree of the target package should be created. This directory must already exist. See the BSgenomeForge vignette in this package for more information.
- `verbose`: `TRUE` or `FALSE`.
- `seqnames`, `mseqnames`:
  - A character vector containing the names of the single (for `seqnames`) and multiple (for `mseqnames`) sequences to forge. See the BSgenomeForge vignette in this package for more information.
prefix, suffix

See the BSgenomeForge vignette in this package for more information, in particular the description of the seqfiles_prefix and seqfiles_suffix fields of a BSgenome data package seed file.

seqs_destdir, masks_destdir

During the forging process the source data files are converted into serialized Biostrings objects. seqs_destdir and masks_destdir must be single strings indicating the path to the directories where these serialized objects should be saved. These directories must already exist.

forgeSeqlengthsFile will produce a single .rda file. Both forgeSeqFiles and forgeMasksFiles will produce one .rda file per sequence.

nmask_per_seq

A single integer indicating the desired number of masks per sequence. See the BSgenomeForge vignette in this package for more information.

Details

These functions are intended for Bioconductor users who want to make a new BSgenome data package, not for regular users of these packages. See the BSgenomeForge vignette in this package (vignette("BSgenomeForge")) for an extensive coverage of this topic.

Author(s)

H. Pages

Examples

```r
forgeSeqFiles("chrM", prefix="ce2", suffix=".fa",
  seqs_srcdir=system.file("extdata", package="BSgenome"),
  seqs_destdir=tempdir())
load(file.path(tempdir(), "chrM.rda"))
chrM
```

Description

Get the list of BSgenome data packages that are currently available on the Bioconductor repositories for your version of R/Bioconductor.

Usage

```r
available.genomes(type=getOption("pkgType"))
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Character string indicating the type of package (&quot;source&quot;, &quot;mac.binary&quot; or &quot;win.binary&quot;) to look for.</td>
</tr>
</tbody>
</table>
bsapply

Details

A BSgenome data package contains the full genome for a given organism. Its name has 4 parts separated by a dot (e.g. BSgenome.Celegans.UCSC.ce2). The 1st part is always BSgenome, the 2nd part is the name of the organism (abbreviated), the 3rd part is the name of the organisation who assembled the genome and the 4th part is the release string or number used by this organisation for this genome. A BSgenome data package contains a single BSgenome object named like the second part of the package name (e.g. Celegans in the case of BSgenome.Celegans.UCSC.ce2) where all the sequences for this genome are stored.

Value

A character vector containing the names of the BSgenome data packages currently available.

BSgenome-class, available.packages

Examples

# Get the list of BSgenome data packages currently available:
available.genomes()

# Make your choice and install with:
source("http://bioconductor.org/biocLite.R")
biocLite("BSgenome.Celegans.UCSC.ce2")

# Have a coffee ;-)  

# Load the package and display the index of sequences for this genome:
library(BSgenome.Celegans.UCSC.ce2)
Celegans

Description

Apply a function to each chromosome in a genome.

Usage

bsapply(BSParams, ...)

Arguments

BSParams a BSParams object that holds the various parameters needed to configure the bsapply function

... optional arguments to `FUN`.  

bsapply

bsapply
Details

By default the exclude parameter is set to not exclude anything. A popular option will probably be to set this to "rand" so that random bits of unassigned contigs are filtered out.

Value

A named list is returned where each element is whatever was returned by the function FUN. The names of the list correspond to the names of the chromosomes as they were labeled by the BSgenome object in the slot accessed by seqnames().

BSgenome-class

Examples

```r
# Load the Worm genome:
library("BSgenome.Celegans.UCSC.ce2")

# Count the alphabet frequencies for every chromosome but exclude
# mitochondrial ones:
params <- new("BSParams", X = Celegans, FUN = alphabetFrequency,
               exclude = "M")
bsapply(params)

# Or we can do this same function with the simplify option:
params <- new("BSParams", X = Celegans, FUN = alphabetFrequency,
               exclude = "M", simplify = TRUE)
bsapply(params)

# Examples to show how we might look for a string (in this case an
ebox motif) across the whole genome.
Ebox <- DNAStringSet("CACGTG")
pdict0 <- PDict(Ebox)
params <- new("BSParams", X = Celegans, FUN = countPDict, simplify = TRUE)
bsapply(params, pdict = pdict0)
params@FUN <- matchPDict
bsapply(params, pdict = pdict0)

# And since its really overkill to use matchPDict to find a single pattern:
params@FUN <- matchPattern
bsapply(params, pattern = "CACGTG")

# Examples on how to use the masks
library("BSgenome.Hsapiens.UCSC.hg18")
# I can make things verbose if I want to see the chromosomes getting processed.
options(verbose=TRUE)
# For the 1st example, lets use default masks
params <- new("BSParams", X = Hsapiens, FUN = alphabetFrequency,
               exclude = c(1:8,"random","hap"), simplify = TRUE)
```
getSeq

bsapply(params)

## Enable all masks
params@maskList <- c("RM"=TRUE,"TRF"=TRUE)
bsapply(params)

## Disable all masks
params@maskList <- c("AGAPS"=FALSE,"AMB"=FALSE)
bsapply(params)

describe getSeq

description

A convenience function for extracting a set of sequences (or subsequences) from a BSgenome object.

Usage

gseq(bseq, names, start=NA, end=NA, width=NA, as.character=TRUE)

Arguments

bsgenome: A BSgenome object. See the available.genomes function for how to install a genome.

names: The names of the sequences to extract from bsgenome. If missing, then seqnames(bsgenome) is used.

See ?seqnames and ?mseqnames to get the list of single sequences and multiple sequences (respectively) contained in bsgenome.

Here is how the lookup between the names passed to the names argument and the sequences in bsgenome is performed. For each name in names: (1) if bsgenome contains a single sequence with that name then this sequence is returned; (2) otherwise the names of all the elements in all the multiple sequences are searched: name is treated as a regular expression and grep is used for this search. If exactly one sequence is found, then it’s returned, otherwise an error is raised.

start, end, width

Specify these arguments only if you don’t want to extract the entire sequences.

Then the subsequences specified by start, end and width (single integers or NAs) will be extracted by a call to subseq before they are returned by getSeq.

as.character: TRUE or FALSE. Should the extracted sequences be returned in a standard character vector?

Value

A standard character vector when as.character=TRUE. Note that when as.character=TRUE, then the masks that are defined on top of the sequences to extract are ignored if any (see ?MaskedXString-class for more information about masked sequences).

A DNAString or MaskedDNAString object when as.character=FALSE. Note that as.character=FALSE is not supported when more than one sequence name is supplied.
Note

Be aware that using `as.character=TRUE` can be very inefficient when the returned character vector contains very long strings (> 1 million letters) or is itself a long vector (> 10000 strings).

`getSeq` is much more efficient when used with `as.character=FALSE` but this works only for extracting one sequence at a time for now.

See Also

`available.genomes`, `BSgenome-class`, `seqnames`, `mseqnames`, `grep`, `subseq`, `DNAString`, `MaskedDNAString`, `[]`, `BSgenome-method`

Examples

```r
# Load the Caenorhabditis elegans genome (UCSC Release ce2):
library(BSgenome.Celegans.UCSC.ce2)

# Look at the index of sequences:
Celegans

# Get chromosome V as a DNAString object:
getSeq(Celegans, "chrV", as.character=FALSE)
# which is in fact the same as doing:
Celegans$chrV

# Never try this:
# getSeq(Celegans, "chrV")
# or this (even worse):
# getSeq(Celegans)

# Get the first 20 bases of each chromosome:
getSeq(Celegans, end=20)

# Get the last 20 bases of each chromosome:
getSeq(Celegans, start=-20)

# Get the "NM_058280_up_1000" sequence (belongs to the upstream1000 multiple sequence) as a character string:
s1 <- getSeq(Celegans, "NM_058280_up_1000")
# or a DNAString object (more efficient):
s2 <- getSeq(Celegans, "NM_058280_up_1000", as.character=FALSE)

getSeq(Celegans, "NM_058280_up_5000", start=-1000) == s1 # TRUE
getSeq(Celegans, "NM_058280_up_5000", start=-1000, as.character=FALSE) == s2 # TRUE
```
injectSNPs: SNP injection

Description

Inject SNPs from a SNPlocs data package into a genome.

Usage

```r
available.SNPs(type=getOption("pkgType"))
injectSNPs(x, SNPlocs_pkgname)
```

## Related utilities

```r
SNPlocs_pkgname(x)
SNPcount(x)
SNPlocs(x, seqname)
```

Arguments

- **type**: Character string indicating the type of package ("source", "mac.binary" or "win.binary") to look for.
- **x**: A BSgenome object.
- **SNPlocs_pkgname**: The name of a SNPlocs data package containing SNP information for the single sequences contained in x. This package must be already installed (injectSNPs won’t try to install it).
- **seqname**: The name of a single sequence in x.

Value

- `available.SNPs` returns a character vector containing the names of the SNPlocs data packages that are currently available on the Bioconductor repositories for your version of R/Bioconductor. A SNPlocs data package contains basic SNP information (location and alleles) for a given organism.
- `injectSNPs` returns a copy of the original genome x where some or all of the single sequences were altered by injecting the SNPs defined in the SNPlocs_pkgname package.
- `SNPlocs_pkgname`, `SNPcount` and `SNPlocs` return NULL if no SNPs were injected in x (i.e. if x is not a BSgenome object returned by a previous call to injectSNPs). Otherwise `SNPlocs_pkgname` returns the name of the package from which the SNPs were injected, `SNPcount` the number of SNPs for each altered sequence in x, and `SNPlocs` their locations in the sequence whose name is specified by seqname.

Note

- `injectSNPs`, `SNPlocs_pkgname`, `SNPcount` and `SNPlocs` have the side effect to try to load the SNPlocs data package if it’s not already loaded.
