GDS-class

Class "GDS"

Description
A class describing a GEO GDS entity

Objects from the Class
Objects can be created by calls of the form new("GDS", ...)

Slots
- gpl: Object of class "GPL"
- dataTable: Object of class "GEODataTable" containing the data table for the GDS
- header: Object of class "list" containing the metadata for the GDS; can be accessed via the Meta accessor

Extends
Class "GEOData", directly.

Methods
No methods defined with class "GDS" in the signature, but methods applying to GEOData are also applicable here.

Author(s)
Sean Davis

See Also

GEOData-class
Converting

Convert a GDS data structure to a BioConductor data structure

Description

Functions to take a GDS data structure from getGEO and coerce it to limma MALists or ExpressionSets.

Usage

GDS2MA(GDS, do.log2=FALSE, GPL=NULL, AnnotGPL=TRUE)
GDS2eSet(GDS, do.log2=FALSE, GPL=NULL, AnnotGPL=TRUE)

Arguments

GDS

The GDS datastructure returned by getGEO

do.log2

Boolean, should the data in the GDS be log2 transformed before inserting into the new data structure

GPL

Either a GPL data structure (from a call to getGEO) or NULL. If NULL, this will cause a call to getGEO to produce a GPL. The gene information from the GPL is then used to construct the genes slot of the resulting limma MAList object or the featureData slot of the ExpressionSet instance.

AnnotGPL

In general, the annotation GPL files will be available for GDS records, so the default is to use these files over the user-submitted GPL files

Details

This function just rearranges one data structure into another. For GDS, it also deals appropriately with making the "targets" list item for the limma data structure and the phenoData slot of ExpressionSets.

Value

GDS2MA

A limma MAList

GDS2eSet

An ExpressionSet object

Author(s)

Sean Davis

References

See the limma and ExpressionSet help in the appropriate packages

Examples

```r
## Not run: gds505 <- getGEO('GDS505')
## Not run: MA <- GDS2MA(gds505)
## Not run: eset <- GDS2eSet(gds505)
```
**Description**

A virtual class for holding GEO samples, platforms, and datasets.

**Objects from the Class**

Objects can be created by calls of the form `new("GEOData", ...).

**Slots**

- **header**: Object of class "list" containing metadata.

**Methods**

- **Accession** signature(object = "GEOData"): returns the GEO accession for the current object.
- **Columns** signature(object = "GEOData"): returns the column descriptions for the current object.
- **Meta** signature(object = "GEOData"): returns the metadata for the current object.
- **Table** signature(object = "GEOData"): returns the "Table" for the current object.
- **dataTable** signature(object = "GEOData"): returns the dataTable (column info and data) for the current object.
- **show** signature(object = "GEOData"): a convenience method for showing a GEO object.

**Author(s)**

Sean Davis

**See Also**

`GDS-class, GPL-class, GSM-class, GEODataTable-class`.

---

**Description**

Contains the column descriptions and data for the datatable part of a GEO object.

**Objects from the Class**

Objects can be created by calls of the form `new("GEODataTable", ...).`
Slots

- **columns**: Object of class "data.frame" containing information about the columns in the datatable.
- **table**: Object of class "data.frame" containing the actual data.

Methods

- **Columns** signature(object = "GEODataTable"): get the column portion of the GEODataTable.
- **Table** signature(object = "GEODataTable"): get the table portion of the GEODataTable.
- **show** signature(object = "GEODataTable"): convenience show method.

Author(s)

- Sean Davis

Description

Contains a full GEO Platform entity.

Objects from the Class

Objects can be created by calls of the form `new("GPL", ...)`. 

Slots

- **dataTable**: Object of class "GEODataTable".
- **header**: Object of class "list." containing metadata associated with the GPL.

Extends

Class "GEOData", directly.

Methods

No methods defined with class "GPL" in the signature, but methods applicable to GEOData are also applicable here.

Author(s)

- Sean Davis

See Also

- **GEOData-class**
**GSE-class**

**Class "GSE"**

**Description**

Contains a GEO Series entity

**Objects from the Class**

Objects can be created by calls of the form `new("GSE", ...)`. 

**Slots**

- `header`: Object of class "list" containing metadata for the series
- `gsms`: Object of class "list" containing a list of items of class GSM associated with the series
- `gpls`: Object of class "list" containing a list of items of class GPL associate with the series

**Methods**

- `GPLList signature(object = "GSE")`: returns a list, each item of the list being a GPL object
- `GSMLList signature(object = "GSE")`: returns a list, each item of the list being a GSM object
- `Meta signature(object = "GSE")`: returns a list, the metadata associated with the GSE

**Author(s)**

Sean Davis

**See Also**

GPL-class, GSM-class

---

**GSM-class**

**Class "GSM"**

**Description**

A class containing a GEO Sample entity

**Objects from the Class**

Objects can be created by calls of the form `new("GSM", ...)`. 

**Slots**

- `dataTable`: Object of class "GEODataTable"
- `header`: Object of class "list" containing the metadata associated with the sample
getGEO

Extends

Class "GEOData", directly.

Methods

No methods defined with class "GSM" in the signature, but methods that apply to the GEOData also apply here.

getGEO  Get a GEO object from NCBI or file

Description

This function is the main user-level function in the GEOquery package. It directs the download (if no filename is specified) and parsing of a GEO SOFT format file into an R data structure specifically designed to make access to each of the important parts of the GEO SOFT format easily accessible.

Usage

getGEO(GEO = NULL, filename = NULL, destdir = tempdir(), GSElimits=NULL, GSEMatrix=TRUE, AnnotGPL=FALSE)
getGEO

Arguments

GEO A character string representing a GEO object for download and parsing. (eg., 'GDS505','GSE2','GSM2','GPL96')

filename The filename of a previously downloaded GEO SOFT format file or its gzipped representation (in which case the filename must end in .gz). Either one of GEO or filename may be specified, not both. GEO series matrix files are also handled. Note that since a single file is being parsed, the return value is not a list of esets, but a single eset when GSE matrix files are parsed.

destdir The destination directory for any downloads. Defaults to the architecture-dependent tempdir. You may want to specify a different directory if you want to save the file for later use. Doing so is a good idea if you have a slow connection, as some of the GEO files are HUGE!

GSElimits This argument can be used to load only a contiguous subset of the GSMs from a GSE. It should be specified as a vector of length 2 specifying the start and end (inclusive) GSMs to load. This could be useful for splitting up large GSEs into more manageable parts, for example.

GSEMatrix A boolean telling GEOquery whether or not to use GSE Series Matrix files from GEO. The parsing of these files can be many orders-of-magnitude faster than parsing the GEO SOFT format files. Defaults to TRUE, meaning that the SOFT format parsing will not occur; set to FALSE if you for some reason need other columns from the GSE records.

AnnotGPL A boolean defaulting to FALSE as to whether or not to use the Annotation GPL information. These files are nice to use because they contain up-to-date information remapped from Entrez Gene on a regular basis. However, they do not exist for all GPLs; in general, they are only available for GPLs referenced by a GDS

Details

getGEO functions to download and parse information available from NCBI GEO (http://www.ncbi.nlm.nih.gov/geo). Here are some details about what is available from GEO. All entity types are handled by getGEO and essentially any information in the GEO SOFT format is reflected in the resulting data structure.

From the GEO website:

The Gene Expression Omnibus (GEO) from NCBI serves as a public repository for a wide range of high-throughput experimental data. These data include single and dual channel microarray-based experiments measuring mRNA, genomic DNA, and protein abundance, as well as non-array techniques such as serial analysis of gene expression (SAGE), and mass spectrometry proteomic data. At the most basic level of organization of GEO, there are three entity types that may be supplied by users: Platforms, Samples, and Series. Additionally, there is a curated entity called a GEO dataset.

A Platform record describes the list of elements on the array (e.g., cDNAs, oligonucleotide probe-sets, ORFs, antibodies) or the list of elements that may be detected and quantified in that experiment (e.g., SAGE tags, peptides). Each Platform record is assigned a unique and stable GEO accession number (GPLxxx). A Platform may reference many Samples that have been submitted by multiple submitters.

A Sample record describes the conditions under which an individual Sample was handled, the manipulations it underwent, and the abundance measurement of each element derived from it. Each Sample record is assigned a unique and stable GEO accession number (GSMxxx). A Sample entity must reference only one Platform and may be included in multiple Series.
getGEOSuppFiles

A Series record defines a set of related Samples considered to be part of a group, how the Samples are related, and if and how they are ordered. A Series provides a focal point and description of the experiment as a whole. Series records may also contain tables describing extracted data, summary conclusions, or analyses. Each Series record is assigned a unique and stable GEO accession number (GSExxx).

GEO DataSets (GDSxxx) are curated sets of GEO Sample data. A GDS record represents a collection of biologically and statistically comparable GEO Samples and forms the basis of GEO’s suite of data display and analysis tools. Samples within a GDS refer to the same Platform, that is, they share a common set of probe elements. Value measurements for each Sample within a GDS are assumed to be calculated in an equivalent manner, that is, considerations such as background processing and normalization are consistent across the dataset. Information reflecting experimental design is provided through GDS subsets.

Value

An object of the appropriate class (GDS, GPL, GSM, or GSE) is returned. If the GSEMatrix option is used, then a list of ExpressionSet objects is returned, one for each SeriesMatrix file associated with the GSE accession. If the filename argument is used in combination with a GSEMatrix file, then the return value is a single ExpressionSet.

Warning

Some of the files that are downloaded, particularly those associated with GSE entries from GEO are absolutely ENORMOUS and parsing them can take quite some time and memory. So, particularly when working with large GSE entries, expect that you may need a good chunk of memory and that coffee may be involved when parsing....

getGEOfile

Examples

```r
  gds <- getGEO("GDS10")
  gds
```

---

getGEOSuppFiles Get Supplemental Files from GEO

Description

NCBI GEO allows supplemental files to be attached to GEO Series (GSE), GEO platforms (GPL), and GEO samples (GSM). This function "knows" how to get these files based on the GEO accession. No parsing of the downloaded files is attempted, since the file format is not generally knowable by the computer.
**getGEOfile**

**Usage**

```r
getGEOsuppFiles(GEO, makeDirectory = TRUE, baseDir = getwd())
```

**Arguments**

- **GEO**: A GEO accession number such as GPL1073 or GSM1137
- **makeDirectory**: Should a "subdirectory" for the downloaded files be created? Default is TRUE. If FALSE, the files will be downloaded directly into the baseDir.
- **baseDir**: The base directory for the downloads. Default is the current working directory.

**Details**

Again, just a note that the files are simply downloaded.

**Value**

A data frame is returned invisibly with rownames representing the full path of the resulting downloaded files and the records in the data.frame the output of file.info for each downloaded file.

**Author(s)**

Sean Davis <sdavis2@mail.nih.gov>

**Examples**

```r
a <- getGEOsuppFiles('GSM1137')
a
```

---

**getGEOfile**  
*Download a file from GEO soft file to the local machine*

**Description**

This function simply downloads a SOFT format file associated with the GEO accession number given.

**Usage**

```r
getGEOfile(GEO, destdir = tempdir(), AnnotGPL = FALSE, amount = c("full", "brief", "quick", "data"))
```

**Arguments**

- **GEO**: Character string, the GEO accession for download (e.g., GDS84, GPL96, GSE2553, or GSM10)
- **destdir**: Directory in which to store the resulting downloaded file. Defaults to tempdir()
- **AnnotGPL**: A boolean defaulting to FALSE as to whether or not to use the Annotation GPL information. These files are nice to use because they contain up-to-date information remapped from Entrez Gene on a regular basis. However, they do not exist for all GPLs; in general, they are only available for GPLs referenced by a GDS
- **amount**: Amount of information to pull from GEO. Only applies to GSE, GPL, or GSM. See details...
Details

This function downloads GEO SOFT files based on accession number. It does not do any parsing. The first two arguments should be fairly self-explanatory, but the last is based on the input to the acc.cgi url at the geo website. In the default “full” mode, the entire SOFT format file is downloaded. Both "brief" and "quick" offer shortened versions of the files, good for "peeking" at the file before a big download on a slow connection. Finally, "data" downloads only the data table part of the SOFT file and is good for downloading a simple EXCEL-like file for use with other programs (a convenience).

Value

Invisibly returns the full path of the downloaded file.

getGEO

Examples

myfile <- getGEOfile('GDS10')

---

gunzip

Gunzip a file

Description

gunzip a file

Usage

gunzip(filename, destname = gsub("[.]gz$", ",", filename), overwrite = FALSE, remove = TRUE, BFR.SIZE = 1e+07)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>The filename to be unzipped</td>
</tr>
<tr>
<td>destname</td>
<td>The destination file</td>
</tr>
<tr>
<td>overwrite</td>
<td>Boolean indicating whether or not to overwrite a destfile of the same name</td>
</tr>
<tr>
<td>remove</td>
<td>Boolean indicating whether or not to remove the original file after completion</td>
</tr>
<tr>
<td>BFR.SIZE</td>
<td>The size of the read buffer....</td>
</tr>
</tbody>
</table>

Details

This function was stripped out of R.utils due to breaking some stuff on the bioconductor build machine.
parseGEO

Value
Invisibly, the number of bytes read.

Author(s)
Original author: Henrik Bengtsson

gzfile

parseGEO | Parse GEO text

Description
Workhorse GEO parsers.

Usage
parseGEO(con, GSElimits)
parseGPL(con)
parseGDS(con)
parseGSE(con, GSElimits)
parseGSM(con)

Arguments
con A connection that contains the body of a GEO SOFT format file
GSElimits Used to limit the number of GSMs parsed into the GSE object; useful for memory management for large GSEs.

Details
These are probably not useful to the end-user. Use getGEO to access these functions. parseGEO simply delegates to the appropriate specific parser. There should be no reason to use the parseGPL, parseGDS, parseGSE, or parseGSM functions directly.

Value
parseGEO returns an object of the associated type. For example, if it is passed the text from a GDS entry, a GDS object is returned.
