actionItem-class

Class "actionItem"

Description

Class and method to capture standard operations in a flow cytometry workflow.

Details

actionItems provide a means to bind standard operations on flow cytometry data in a workflow. Usually, the user doesn’t have to create these objects, instead they will be automatically created when applying one of the standard operations (gating, transformation, compensation) to a workFlow object. Each actionItem creates one or several new views, which again can be the basis to apply further operations. One can conceptualize actionItems being the edges in the workflow tree connecting views, which are the nodes of the tree. There are more specific subclasses for the three possible types of operation: gateActionItem for gating operations, transformActionItem for transformations, and compensateActionItem for compensation operations. See their documentation for details.

Objects from the Class

A virtual Class: No objects may be created from it.

Slots

ID: Object of class "character". A unique identifier for the actionItem.

name: Object of class "character". A more human-readable name

parentView: Object of class "fcViewReference". A reference to the parent view the actionItem is applied on.

env: Object of class "environment". The evaluation environment in the workFlow.
arcsinhTransform

Methods

  identifier signature(object = "actionItem"): Accessor for the ID slot.
  names signature(x = "actionItem"): Accessor for the name slot.
  parent signature(object = "actionItem"): Accessor for the parentView slot. Note that the reference is resolved, i.e., the view object is returned.
  alias signature(object = "actionItem"): Get the alias table from a actionItem.
  Rm signature(symbol = "actionItem", envir = "workFlow", subSymbol = "character"): Remove a actionItem from a workFlow. This method is recursive and will also remove all dependent views and actionItems.

Author(s)

Florian Hahne

See Also

workFlow, gateActionItem, transformActionItem, compensateActionItem, view

Examples

  showClass("view")

arcsinhTransform  Create the definition of an arcsinh transformation function (base specified by user) to be applied on a data set

Description

Create the definition of the arcsinh Transformation that will be applied on some parameter via the transform method. The definition of this function is currently x<-asinh(a+b*x)+c). The transformation would normally be used to convert to a linear valued parameter to the natural logarithm scale. By default a and b are both equal to 1 and c to 0.

Usage

  arcsinhTransform(transformationId="defaultArcsinhTransform", a=1, b=1, c=0)

Arguments

  transformationId
    character string to identify the transformation
  a
    positive double that correponds to the base of the logarithm.
  b
    positive double that correponds to a scale factor.
  c
    positive double that correponds to a scale factor

Value

  Returns an object of class transform.
Author(s)

B. Ellis

transform-class, transform, asinh

Examples

samp <- read.FCS(system.file("extdata",  
    "0877408774.B08", package="flowCore"))
asinhTrans <- arcsinhTransform(transformationId="ln-transformation", a=1, b=1, c=1)
dataTransform <- transform(samp, `FSC-H`=asinhTrans(`FSC-H`))

Description

Inverse hyperbolic sine transformation is defined by the function

\[
    f(parameter, a, b) = \sinh^{-1}(a \times parameter) \times b
\]

Objects from the Class

Objects can be created by calls to the constructor asinh (parameter, a, b, transformationId)

Slots

- **.Data**: Object of class "function"
- **a**: Object of class "numeric" - non zero constant
- **b**: Object of class "numeric" - non zero constant
- **parameters**: Object of class "transformation" - flow parameter to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation

Extends

Methods

No methods defined with class "asinh" in the signature.

Note

The inverse hyperbolic sine transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

sinht

Examples
```r
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
asinhl<-asinht(parameters="FSC-H",a=2,b=1,transformationId="asinH1")
transOut<-eval(asinh1)(exprs(dat))
```

---

**biexponentialTransform**

*Compute a transform using the 'biexponential' function*

**Description**

The 'biexponential' is an over-parameterized inverse of the hyperbolic sine. The function to be inverted takes the form biexp(x) = a*exp(b*(x-w))-c*exp(-d*(x-w))+f with default parameters selected to correspond to the hyperbolic sine.

**Usage**

```r
biexponentialTransform(transformationId="defaultBiexponentialTransform", a = 0.5, b = 1, c = 0.5, d = 1, f = 0, w = 0, tol = .Machine$double.eps^0.25, maxit = as.integer(5000))
```

**Arguments**

- `transformationId`
  A name to assign to the transformation. Used by the transform/filter integration routines.
- `a`
  See the function description above. Defaults to 0.5
- `b`
  See the function description above. Defaults to 1.0
- `c`
  See the function description above. Defaults to 0.5 (the same as `a`)
- `d`
  See the function description above. Defaults to 1 (the same as `b`)
- `f`
  A constant bias for the intercept. Defaults to 0.
- `w`
  A constant bias for the 0 point of the data. Defaults to 0.
- `tol`
  A tolerance to pass to the inversion routine (`uniroot` usually)
- `maxit`
  A maximum number of iterations to use, also passed to `uniroot`

**Value**

Returns values giving the inverse of the biexponential within a certain tolerance. This function should be used with care as numerical inversion routines often have problems with the inversion process due to the large range of values that are essentially 0. Do not be surprised if you end up with population splitting about `w` and other odd artifacts.
boundaryFilter-class

Class "boundaryFilter"

Description

Class and constructor for data-driven filter objects that discard margin events.

Usage

boundaryFilter(x, tolerance=.Machine$double.eps, filterId="defaultBoundaryFilter")

Arguments

x Character giving the name of the measurement parameter on which the filter is supposed to work on. This can also be a list containing a single character scalar for programmatic access.

tolerance Numerics scalar, used to set the tolerance slot of the object.

filterId An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.
Details

Flow cytometry instruments usually operate on a given data range, and the limits of this range are stored as keywords in the FSC files. Depending on the amplification settings and the dynamic range of the measured signal, values can occur that are outside of the measurement range, and most instruments will simply pile those values at the minimum or maximum range limit. The `boundaryFilter` removes these values, either for a single parameter, or for a combination of parameters. Note that it is often desirable to treat boundary events on a per-parameter basis, since their values might be uniformative for one particular channel, but still be useful in all of the other channels.

The constructor `boundaryFilter` is a convenience function for object instantiation. Evaluating a `boundaryFilter` results in a single sub-populations, an hence in an object of class `filterResult`.

Value

Returns a `boundaryFilter` object for use in filtering `flowFrame`s or other flow cytometry objects.

Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

tolerance: Object of class "numeric". The machine tolerance used to decide whether an event is on the measurement boundary. Essentially, this is done by evaluating \( x > \text{minRange} + \text{tolerance} \) & \( x < \text{maxRange} - \text{tolerance} \).

Objects from the Class

Objects can be created by calls of the form `new("boundaryFilter", ...)` or using the constructor `boundaryFilter`. Using the constructor is the recommended way of object instantiation:

Methods

\%in\% signature(x = "flowFrame", table = "boundaryFilter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.

show signature(object = "boundaryFilter"): Print information about the filter.

Author(s)

Florian Hahne

See Also

`flowFrame, flowSet, filter` for evaluation of `boundaryFilters` and `Subset` for sub-setting of flow cytometry data sets based on that.
Examples

```r
## Loading example data
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))

## Create directly. Most likely from a command line
boundaryFilter("FSC-H", filterId="myBoundaryFilter")

## To facilitate programmatic construction we also have the following
bf <- boundaryFilter(filterId="myBoundaryFilter", x=list("FSC-H"))

## Filtering using boundaryFilter
fres <- filter(dat, bf)
fres
summary(fres)

## We can subset the data with the result from the filtering operation.
Subset(dat, fres)
```

**characterOrTransformation-class**

*Class* "characterOrTransformation"

Description

~~A concise (1-5 lines) description of what the class is.~~

Objects from the Class

A virtual Class: No objects may be created from it.

Methods

No methods defined with class "characterOrTransformation" in the signature.

Note

~~further notes~~

Author(s)

~~who you are~~

References

~put references to the literature/web site here ~

Examples

```
showClass("characterOrTransformation")
```
coerce

Convert an object to another class

Description

These functions manage the relations that allow coercing an object to a given class.

Arguments

from, to

The classes between which def performs coercion. (In the case of the coerce function, these are objects from the classes, not the names of the classes, but you’re not expected to call coerce directly.)

Details

The function supplied as the third argument is to be called to implement as(x, to) when x has class from. Need we add that the function should return a suitable object with class to.

Author(s)

F. Hahne, B. Ellis

Examples

samp1 <- read.FCS(system.file("extdata","0877408774.E07", package="flowCore"))
samp2 <- read.FCS(system.file("extdata","0877408774.B08",package="flowCore"))
samples <-list("sample1"=samp1,"sample2"=samp2)
experiment <- as(samples,"flowSet")

compensateActionItem-class

Class "compensateActionItem"

Description

Class and method to capture compensation operations in a flow cytometry workflow.

Usage

compensateActionItem(ID = paste("compActionRef", guid(), sep = "_")
, name = paste("action", identifier(get(compensate)), sep = "_")
, parentView, compensate, workflow)
Arguments

workflow  An object of class `workFlow` for which a view is to be created.
ID       A unique identifier of the view, most likely created by using the internal `guid` function.
name     A more human-readable name of the view.
parentView, compensate  References to the parent view and compensation objects, respectively.

Details

`compensateActionItems` provide a means to bind compensation operations in a workflow. Each `compensateActionItem` represents a single compensation.

Value

A reference to the `compensateActionItem` that is created inside the `workFlow` environment as a side effect of calling the `add` method.
A `compensateActionItem` object for the constructor.

Objects from the Class

Objects should be created using the `add` method, which creates a `compensateActionItem` from a `compensation` object and directly assigns it to a `workFlow`. Alternatively, one can use the `compensateActionItem` constructor function for more programmatic access.

Slots

`compensate`: Object of class "fcCompensateReference". A reference to the `compensation` object that is used for the compensation operation.
ID: Object of class "character". A unique identifier for the actionItem.
name: Object of class "character". A more human-readable name
parentView: Object of class "fcViewReference". A reference to the parent view the compensateActionItem is applied on.
env: Object of class "environment". The evaluation environment in the workFlow.

Extends

Class "actionItem", directly.

Methods

print signature(x = "compensateActionItem"): Print details about the object.
Rm signature(symbol = "compensateActionItem", envir = "workFlow", subSymbol = "character"): Remove a compensateActionItem from a workFlow. This method is recursive and will also remove all dependent views and actionItems.
show signature(object = "compensateActionItem"): Print details about the object.

Author(s)

Florian Hahne
See Also

workFlow, actionItem, gateActionItem, transformActionItem, view

Examples

showClass("view")

compensatedParameter-class

Class "compensatedParameter"

Description

Emission spectral overlap can be corrected by subtracting the the amount of spectral overlap from the total detected signals. This compensation process can be described by using spillover matrices. compensatedParameter objects allow for compensation of specific parameters the user is interested in by creating compensatedParameter objects and evaluating them. This allows for use of compensatedParameter in gate definitions.

Objects from the Class

Objects can be created by calls of the form compensatedParameter(parameters, spillRefId, transformationId, searchEnv).

Slots

.Data: Object of class "function" -
parameters: Object of class "character" - flow parameters to be compensated
spillRefId: Object of class "character" - name of the compensation object (The compensation object contains the spillover Matrix)
searchEnv: Object of class "environment" - environment in which the compensation object is defined
transformationId: Object of class "character" - unique Id to reference the compensatedParameter object

Extends

Methods

No methods defined with class "compensatedParameter" in the signature.

Note

The transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)
compensateView-class

compensation

Examples
samp <- read.flowSet(path=system.file("extdata", "compdata", "data", package="flowCore")
cfile <- system.file("extdata", "compdata", "compmatrix", package="flowCore")
comp.mat <- read.table(cfile, header=TRUE, skip=2, check.names = FALSE)
comp.mat

## create a compensation object
comp <- compensation(comp.mat,compensationId="comp1")

## create a compensated parameter object
cPar1<-compensatedParameter(c("FL1-H","FL3-H"),"comp",searchEnv=.GlobalEnv)
compOut<-eval(cPar1){exprs(samp[[1]])}

compensateView-class

Class "compensateView"

Description
Class and method to capture the result of compensation operations in a flow cytometry workflow.

Usage

compensateView(workflow, ID=paste("compViewRef", guid(), sep="_"),
name="default", action, data)

Arguments

workflow An object of class workFlow for which a view is to be created.
ID A unique identifier of the view, most likely created by using the internal guid function.
name A more human-readable name of the view.
data, action References to the data and actionItem objects, respectively.
Value

A reference to the `compensateView` that is created inside the `workFlow` environment as a side effect of calling the `add` method.

A `compensateView` object for the constructor.

Objects from the Class

Objects should be created using the `add` method, which creates a `compensateView` from a `compensation` object and directly assigns it to a `workFlow`. Alternatively, one can use the `compensateView` constructor function for more programmatic access.

Slots

- **ID**: Object of class "character". A unique identifier for the view.
- **name**: Object of class "character". A more human-readable name
- **action**: Object of class "fcActionReference". A reference to the `actionItem` that generated the view.
- **env**: Object of class "environment". The evaluation environment in the `workFlow`.
- **data**: Object of class "fcDataReference" A reference to the data that is associated to the view.

Extends

Class "view", directly.

Methods

- **Rm** signature(symbol = "compensateView", envir = "workFlow", subSymbol = "character"): Remove a `compensateView` from a `workFlow`. This method is recursive and will also remove all dependent views and `actionItems`.

Author(s)

Florian Hahne

See Also

`workFlow, view, gateView, transformView, normalizeView, actionItem`

Examples

`showClass("view")`
Description

Class and methods to compensate for spillover between channels by applying a spillover matrix to
a flowSet or a flowFrame assuming a simple linear combination of values.

Usage

compensation(..., spillover,
compensationId="defaultCompensation")

compensate(x, spillover, ...)

Arguments

spillover The spillover or compensation matrix.
compensationId The identifier for the compensation object.
x An object of class flowFrame or flowSet.
... Further arguments.

The constructor is designed to be useful in both programmatic and interactive
settings, and ... serves as a container for possible arguments. The following
combinations of values are allowed:

Elements in ... are character scalars of parameter names or transform
objects and the colnames in spillover match to these parameter names.
The first element in ... is a character vector of parameter names or a list of
character scalars or transform objects and the colnames in spillover
match to these parameter names.

Argument spillover is missing and the first element in ... is a matrix, in
which case it is assumed to be the spillover matrix.

... is missing, in which case all parameter names are taken from the colnames
of spillover.

Details

The essential premise of compensation is that some fluorochromes may register signals in detectors
that do not correspond to their primary detector (usually a photomultiplier tube). To compensate for
this fact, some sort of standard is used to obtain the background signal (no dye) and the amount of
signal on secondary channels for each fluorochrome relative to the signal on their primary channel.

To calculate the spillover percentage we use either the mean or the median (more often the latter)
of the secondary signal minus the background signal for each dye to obtain n by n matrix, S, of
so-called spillover values, expressed as a percentage of the primary channel. The observed values
are then considered to be a linear combination of the true fluorescence and the spillover from each
other channel so we can obtain the true values by simply multiplying by the inverse of the spillover
matrix.
The spillover matrix can be obtained through several means. Some flow cytometers provide a spillover matrix calculated during acquisition, possibly by the operator, that is made available in the metadata of the flowFrame. While there is a theoretical standard keyword $SPILL it can also be found in the SPILLOVER or SPILL keyword depending on the cytometry. More commonly the spillover matrix is calculated using a series of compensation cells or beads collected before the experiment. If you have set of FCS files with one file per fluorochrome as well as an unstained FCS file you can use the `spillover` method for `flowSets` to automatically calculate a spillover matrix.

The `compensation` class is essentially a wrapper around a matrix that allows for transformed parameters and method dispatch.

**Value**

A `compensation` object for the constructor.

A `flowFrame` or `flowSet` for the `compensate` methods.

**Objects from the Class**

Objects should be created using the constructor `compensation()`. See the `Usage` and `Arguments` sections for details.

**Slots**

- `spillover`: Object of class `matrix`; the spillover matrix.
- `compensationId`: Object of class `character`. An identifier for the object.
- `parameters`: Object of class `parameters`. The flow parameters for which the compensation is defined. This can also be objects of class `transform`, in which case the compensation is performed on the compensated parameters.

**Methods**

- `compensate` signature(x = "flowFrame", spillover = "compensation"): Apply the compensation defined in a compensation object on a `flowFrame`. This returns a compensated `flowFrame`.
  
  **Usage:**
  
  `compensate(flowFrame, compensation)`

- `compensate` signature(x = "flowFrame", spillover = "matrix"): Apply a compensation matrix to a `flowFrame`. This returns a compensated `flowFrame`.
  
  **Usage:**
  
  `compensate(flowFrame, matrix)`

- `compensate` signature(x = "flowFrame", spillover = "data.frame"): Try to coerce the data.frame to a matrix and apply that to a `flowFrame`. This returns a compensated `flowFrame`.
  
  **Usage:**
  
  `compensate(flowFrame, data.frame)`

- `identifier, identifier<-` signature(object = "compensation"): Accessor and replacement methods for the `compensationId` slot.
  
  **Usage:**
  
  `identifier(compensation)`
  
  `identifier(compensation) <- value`
parameters signature(object = "compensation"): Get the parameter names of the compensation object. This method also tries to resolve all transforms and transformReferences before returning the parameters as character vectors. Unresolvable references return NA.

Usage:
parameters(compensation)

show signature(object = "compensation"): Print details about the object.

Usage:
This method is automatically called when the object is printed on the screen.

compensate(samp, comp)
```

concreteFilter-class

Class "concreteFilter"

Description

The concreteFilter serves as a base class for all filters that actually implement a filtering process. At the moment this includes all filters except filterReference, the only non-concrete filter at present.

Objects from the Class

Objects of this class should never be created directly. It serves only as a point of inheritance.

Slots

filterId: The identifier associated with this class.
Curv1Filter-class

Description

Class and constructor for data-driven filter objects that selects high-density regions in one dimension.

Usage

```r
curv1Filter(x, bwFac=1.2, gridsize=rep(401, 2), filterId="defaultCurv1Filter")
```

Arguments

- **x**: Character giving the name of the measurement parameter on which the filter is supposed to work on. This can also be a list containing a single character scalar for programmatic access.
- **filterId**: An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.
- **bwFac, gridsize**: Numerics of length 1 and 2, respectively, used to set the bwFac and gridsize slots of the object.

Details

Areas of high local density in one dimensions are identified by detecting significant curvature regions. See Duong, T. and Cowling, A. and Koch, I. and Wand, M.P., Computational Statistics and Data Analysis 52/9, 2008 for details. The constructor `curv1Filter` is a convenience function for object instantiation. Evaluating a `curv1Filter` results in potentially multiple sub-populations, and hence an object of class `multipleFilterResult`. Accordingly, `curv1Filters` can be used to split flow cytometry data sets.

Value

Returns a `curv1Filter` object for use in filtering `flowFrames` or other flow cytometry objects.
curv1Filter-class

Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

bwFac: Object of class "numeric". The bandwidth factor used for smoothing of the density estimate.
gridsize: Object of class "numeric". The size of the bins used for density estimation.
parameters: Object of class "character", describing the parameter used to filter the flowFrame.
filterId: Object of class "character", referencing the filter.

Objects from the Class

Objects can be created by calls of the form new("curvFilter", ...) or using the constructor curv1Filter. Using the constructor is the recommended way of object instantiation:

Methods

%in% signature(x = "flowFrame", table = "curv1Filter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the filter methods.
show signature(object = "curv1Filter"): Print information about the filter.

Note

See the documentation in the flowViz package for plotting of curv1Filters.

## We can limit the splitting to one or several sub-populations
split(dat, fres, population="rest")
split(dat, fres, population=list(keep=c("peak 2", "peak 3")))

curv2Filter-class  

Class "curv2Filter"

Description

Class and constructor for data-driven filter objects that selects high-density regions in two dimensions.

Usage

curv2Filter(x, y, filterId="defaultCurv2Filter", bwFac=1.2,
gridsize=rep(151, 2))

Arguments

x, y  Characters giving the names of the measurement parameter on which the filter is supposed to work on. y can be missing in which case x is expected to be a character vector of length 2 or a list of characters.

filterId  An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.

bwFac, gridsize  Numerics of length 1 and 2, respectively, used to set the bwFac and gridsize slots of the object.

Details

Areas of high local density in two dimensions are identified by detecting significant curvature regions. See Duong, T. and Cowling, A. and Koch, I. and Wand, M.P., Computational Statistics and Data Analysis 52/9, 2008 for details. The constructor curv2Filter is a convenience function for object instantiation. Evaluating a curv2Filter results in potentially multiple sub-populations, an hence in an object of class multipleFilterResult. Accordingly, curv2Filters can be used to split flow cytometry data sets.

Value

Returns a curv2Filter object for use in filtering flowFrames or other flow cytometry objects.
**curv2Filter-class**

**Extends**

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

**Slots**

- **bwFac**: Object of class "numeric". The bandwidth factor used for smoothing of the density estimate.
- **gridsize**: Object of class "numeric". The size of the bins used for density estimation.
- **parameters**: Object of class "character", describing the parameters used to filter the flowFrame.
- **filterId**: Object of class "character", referencing the filter.

**Objects from the Class**

Objects can be created by calls of the form `new("curv2Filter", ...)` or using the constructor `curv2Filter`. The constructor is the recommended way of object instantiation:

**Methods**

- `%in%` signature(`x = "flowFrame", table = "curv2Filter"`): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.
- `show` signature(`object = "curv2Filter"`): Print information about the filter.

**Note**

See the documentation in the flowViz package for plotting of curv2Filters.

**Author(s)**

Florian Hahne

**See Also**

curv1Filter, flowFrame, flowSet, filter for evaluation of curv2Filters and split for splitting of flow cytometry data sets based on that.

**Examples**

```r
## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Create directly. Most likely from a command line
curv2Filter("FSC-H", "SSC-H", filterId="myCurv2Filter")

## To facilitate programmatic construction we also have the following
c2f <- curv2Filter(filterId="myCurv2Filter", x=list("FSC-H", "SSC-H"), bwFac=2)
c2f <- curv2Filter(filterId="myCurv2Filter", x=c("FSC-H", "SSC-H"), bwFac=2)
```
### Filtering using curv2Filter

```r
define <- filter(dat, c2f)
define
summary(define)
names(define)
```

### The result of curv2 filtering are multiple sub-populations

```r
## and we can split our data set accordingly
split(dat, define)
```

### We can limit the splitting to one or several sub-populations

```r
## We can limit the splitting to one or several sub-populations
split(dat, define, population="rest")
split(dat, define, population=list(keep=c("area 2", "area 3")))
curv2Filter("FSC-H", "SSC-H", filterId="test filter")
```

dg1polynomial-class

**Class** "dg1polynomial"

---

**Description**

dg1polynomial allows for scaling, linear combination and translation within a single transformation defined by the function

\[
f(\text{parameter}_1, ..., \text{parameter}_n, a_1, ..., a_n, b) = b + \sum_{i=1}^{n} a_i \cdot \text{parameter}_i\]

**Objects from the Class**

Objects can be created by using the constructor `dg1polynomial(parameter, a, b, transformationId)`.

**Slots**

**.Data**: Object of class "function"~~

**parameters**: Object of class "parameters" - the flow parameters that are to be transformed

**a**: Object of class "numeric" - coefficients of length equal to the number of flow parameters

**b**: Object of class "numeric" - coefficient of length 1 that performs the translation

**transformationId**: Object of class "character" unique ID to reference the transformation

**Extends**

**Methods**

No methods defined with class "dg1polynomial" in the signature.
Note
The transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

transOut <- eval(dg1)(exprs(dat))

each_col
Method to apply functions over flowFrame margins

Description
Returns a vector or array of values obtained by applying a function to the margins of a flowFrame. This is equivalent of running apply on the output of exprs(flowFrame).

Usage

  each_col(x, FUN, ...)  
  each_row(x, FUN, ...)

Arguments

  x  
  Object of class flowFrame.

  FUN  
  the function to be applied. In the case of functions like `+`, `*`, etc., the function name must be backquoted or quoted.

  ...  
  optional arguments to `FUN`.

```

EHtrans-class  
Class “EHtrans”

Description

EH transformation of a parameter is defined by the function

\[
EH(\text{parameter}, a, b) = 10^{\frac{\text{parameter}}{a}} + \frac{b \cdot \text{parameter}}{a} - 1 \quad \text{parameter} \geq 0
\]

\[
-10^{\frac{-\text{parameter}}{a}} + \frac{b \cdot \text{parameter}}{a} + 1 \quad \text{parameter} < 0
\]

Objects from the Class

Objects can be created by calls to the constructor `EHtrans(parameters,a,b,transformationId)`

Slots

- **.Data**: Object of class "function" 
- **a**: Object of class "numeric" - numeric constant greater than zero
- **b**: Object of class "numeric" - numeric constant greater than zero
- **parameters**: Object of class "transformation" - flow parameter to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation

Extends

Methods

No methods defined with class "EHtrans" in the signature.

Note

The transformation object can be evaluated using the `eval` method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

transOut<-eval(ehl)(exprs(dat))

ellipsoidGate-class

Class "ellipsoidGate"

Description
Class and constructor for n-dimensional ellipsoidal filter objects.

Usage

ellipsoidGate(...) .gate, mean, distance=1, filterId="defaultEllipsoidGate")

Arguments

filterId An optional parameter that sets the filterId of this gate.
.gate A definition of the gate via a covariance matrix.
mean Numeric vector of equal length as dimensions in .gate.
distance Numeric scalar giving the Mahalanobis distance defining the size of the ellipse. This mostly exists for compliance reasons to the gatingML standard as mean and gate should already uniquely define the ellipse. Essentially, distance is merely a factor that gets applied to the values in the covariance matrix.
...

You can also directly describe the covariance matrix through named arguments, as described below.
Details

A convenience method to facilitate the construction of a ellipsoid \texttt{filter} objects. Ellipsoid gates in \(n\) dimensions (\(n \geq 2\)) are specified by a a covarinace matrix and a vector of mean values giving the center of the ellipse.

This function is designed to be useful in both direct and programmatic usage. In the first case, simply describe the covariance matrix through named arguments. To use this function programmatically, you may pass a covariance matrix and a mean vector directly, in which case the parameter names are the colnames of the matrix.

Value

Returns a \texttt{ellipsoidGate} object for use in filtering \texttt{flowFrames} or other flow cytometry objects.

Extends

Class "\texttt{parameterFilter}"., directly.
Class "\texttt{concreteFilter}"., by class \texttt{parameterFilter}, distance 2.
Class "\texttt{filter}"., by class \texttt{parameterFilter}, distance 3.

Slots

- \texttt{mean}: Objects of class "\texttt{numeric}". Vector giving the location of the center of the ellipse in \(n\) dimensions.
- \texttt{cov}: Objects of class "\texttt{matrix}". The covariance matrix defining the shape of the ellipse.
- \texttt{distance}: Objects of class "\texttt{numeric}". The Mahalanobis distance defining the size of the ellipse.
- \texttt{parameters}: Object of class "\texttt{character}"., describing the parameter used to filter the \texttt{flowFrame}.
- \texttt{filterId}: Object of class "\texttt{character}"., referencing the filter.

...: You can also directly describe the covarinace matrix of the \texttt{ellipsoidGate} through named arguments, as described below.

Objects from the Class

Objects can be created by calls of the form \texttt{new("ellipsoidGate", ...)} or by using the constructor \texttt{ellipsoidGate}. Using the constructor is the recommended way of object instantiation:

Methods

- \texttt{\%in\%} \texttt{signature(x = "flowFrame", table = "ellipsoidGate")}: The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the \texttt{filter} methods.

- \texttt{show} \texttt{signature(object = "ellipsoidGate")}: Print information about the filter.

Note

See the documentation in the \texttt{flowViz} package for plotting of \texttt{ellipsoidGates}.

**exponential-class**  *Class* "exponential"

**Description**

Exponential transform class defines a transformation given by the function

\[
f(\text{parameter}, a, b) = e^{\text{parameter}/b} * \frac{1}{a}
\]

**Objects from the Class**

Objects can be created by calls to the constructor `exponential(parameters,a,b)`.
Slots

- **.Data**: Object of class "function".
- **a**: Object of class "numeric"- non zero constant
- **b**: Object of class "numeric"- non zero constant
- **parameters**: Object of class "transformation"- flow parameter to be transformed
- **transformationId**: Object of class "character" -unique ID to reference the transformation

Extends

Methods

No methods defined with class "exponential" in the signature.

Note

The exponential transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column.

expressionFilter-class

Class "expressionFilter"

Description
A filter holding an expression that can be evaluated to a logical vector or a vector of factors.

Usage

expressionFilter(expr, ..., filterId="defaultExpressionFilter")
char2ExpressionFilter(expr, ..., filterId="defaultExpressionFilter")

Arguments

filterId  An optional parameter that sets the filterId of this filter. The object can later be identified by this name.
expr     A valid R expression or a character vector that can be parsed into an expression.
...     Additional arguments that are passed to the evaluation environment of the expression.

Details
The expression is evaluated in the environment of the flow cytometry values, hence the parameters of a flowFrame can be accessed through regular R symbols. The convenience function char2ExpressionFilter exists to programmatically construct expressions.

Value
Returns a expressionFilter object for use in filtering flowFrames or other flow cytometry objects.

Extends
Class "concreteFilter", directly.
Class "filter", by class concreteFilter, distance 2.

Slots

expr: The expression that will be evaluated in the context of the flow cytometry values.
args: An environment providing additional parameters.
filterId: The identifier of the filter

Objects from the Class
Objects can be created by calls of the form new("expressionFilter", ...), using the expressionFilter constructor or, programmatically, from a character string using the char2ExpressionFilter function.
Methods

%in% signature(x = "flowFrame", table = "expressionFilter"): The workhorse used to evaluate the gate on data. This is usually not called directly by the user, but internally by calls to the filter methods.

show signature(object = "expressionFilter"): Print information about the gate.

fcTransformReference <- function(ID=paste("transRef",
                                              guid(), sep="_"),
                                              env=new.env(parent=emptyenv()))
fcNullReference <- function(...) new("fcNullReference")
assign(x, value, pos = -1, envir = as.environment(pos), inherits = FALSE, immediate = TRUE)
get(x, pos = -1, envir = as.environment(pos), mode = "any", inherits = TRUE)
isNull(f)
Rm(symbol, envir, subSymbol, ...)

Arguments
x, f, symbol An object of class or inheriting from class fcReference.
value An arbitrary R object which is supposed to be assigned to the environment in the workFlow object and to which a reference is returned.
env An environment, usually within a workFlow object.
pos, envir Objects of class workFlow.
inherits, immediate, mode, subSymbol, ...
Further arguments from the generics that are not used in this context.

Details
These classes provide references to objects within an R environment and allow for method dispatch based on the nature of the referenced object. The parent fcReference class is used for references to all R objects, unless there exists a more specific subclass. fcTreeReference, fcViewReference, and fcActionReference are used to reference to graphNEL, view, and actionItem objects, respectively. fcDataReference should be used for flowFrame or flowSet objects, whereas fcFilterResultReference, fcFilterReference, fcTransformReference, fcCompensateReference, and fcNormalizationReference link to filterResult, filter, transform and compensation objects. fsStructureReference only exists to jointly dispatch on certain subgroups of references.

Value
An object of class fcReference or one of its subclasses for the assign constructor.
The object referenced to for the get method.
A character string of the object symbol for the identifier method.
A logical scalar for the isNull method.

Extends
fcStructureReference:

Class "fcReference", directly.

fcTransformReference:
Class "fcReference", directly.

fcNormalizationReference:
Class "fcReference", directly.

fcNullReference:

Objects from the Class

Objects should be created via the assign constructor. Whenever an object is assigned to a workFlow using the assign method, an appropriate instance of class fcReference or one of its subclasses is returned. In addition, there are the usual constructor functions of same names as the classes that can be used for object instantiation without assignment. Note that this might lead to unresolvable references unless the object referenced to is available in the environment.
Slots

- **ID**: Object of class "character" The name of the object in env referenced to.
- **env**: Object of class "environment" An environment that contains the referenced objects. Usually, this will be the environment that’s part of a `workFlow` object.

Methods

- **get** signature(x = "fcReference", pos = "missing", envir = "missing", mode = "missing", inherits = "missing"): Resolve the reference, i.e., get the object from the environment.
- **get** signature(x = "fcNullReference", pos = "missing", envir = "missing", mode = "missing", inherits = "missing"): Resolve the reference. This always returns NULL.
- **identifier** signature(object = "fcReference"): Return a character string of the object name.
- **isNull** signature(f = "fcReference"): Check whether a fcReference is a NULL reference. Note that this is different from a unresolvable reference.
- **Rm** signature(symbol = "fcReference", envir = "missing", subSymbol = "character"): Remove the object referenced to by a fcReference from its environment. The argument subSymbol will be automatically set by the generic and should never be provided by the user.
- **Rm** signature(symbol = "fcNullReference", envir = "workFlow", subSymbol = "character"): Remove the object referenced to by a fcReference from a `workFlow`. The argument subSymbol will be automatically set by the generic and should never be provided by the user.
- **Rm** signature(symbol = "fcNullReference", envir = "missing", subSymbol = "character"): Essentially, this doesn’t do anything since there is no object referenced to.
- **show** signature(object = "fcReference"): Print details about the object.
- **show** signature(object = "fcNullReference"): Print details about the object.

**filter-and-methods**  
Take the intersection of two filters

**Description**

There are two notions of intersection in flowCore. First, there is the usual intersection boolean operator \& that has been overridden to allow the intersection of two filters or of a filter and a list for convenience. There is also the %\&% or %subset% operator that takes an intersection, but with subset semantics rather than simple intersection semantics. In other words, when taking a subset, calculations from summary and other methods are taken with respect to the right hand filter. This primarily affects percentage calculations, which are ordinarily calculated with respect to the entire population as well as data-driven gating procedures which will operate only on elements contained by the right hand filter. This becomes especially important when using filters such as norm2Filter.

**Author(s)**

B. Ellis

---

**filter-class**  
A class for representing filtering operations to be applied to flow data.

**Description**

The filter class is the virtual base class for all filter/gating objects in flowCore. In general you will want to subclass or create a more specific filter.

**Slots**

*filterId*: A character vector that identifies this filter. This is typically user specified but can be automatically deduced by certain filter operations, particularly boolean and set operations.

**Objects from the Class**

All *filter* objects in flowCore should be instantiated through their constructors. These are functions that share the same name with the respective filter classes. E.g., `rectangleGate()` (rectangleGate) is the constructor function for rectangular gates, and `kmeansFilter()` (kmeansFilter) creates objects of class `kmeansFilter`. Usually these constructors can deal with various different inputs, allowing to utilize the same function in different programmatic or interactive settings. For all filters that operate on specific flow parameters (i.e., those inheriting from parameterFilter), the parameters need to be passed to the constructor, either as names or colnames of additional input arguments or explicitely as separate arguments. See the documentation of the respective filter classes for details. If parameters are explicitely defined as separate arguments, they may be of class character, in which case they will be evaluated literaly as colnames in a flowFrame, or of class transform, in which case the filtering is performed on a temporarily transformed copy of the input data. See here for details.
Methods

%in% Used in the usual way this returns a vector of values that identify which events were accepted by the filter. A single filter may encode several populations so this can return either a logical vector, a factor vector or a numeric vector of probabilities that the event is accepted by the filter. Minimally, you must implement this method when creating a new type of filter

&, |, ! Two filters can be composed using the usual boolean operations returning a filter class of a type appropriate for handling the operation. These methods attempt to guess an appropriate filterId for the new filter

%subset%, %&% Defines a filter as being a subset of another filter. For deterministic filters the results will typically be equivalent to using an & operation to compose the two filters, though summary methods will use subset semantics when calculating proportions. Additionally, when the filter is data driven, such as norm2Filter, the subset semantics are applied to the data used to fit the filter possibly resulting in quite different, and usually more desirable, results.

%on% Used in conjunction with a transformList to create a transformFilter. This filter is similar to the subset filter in that the filtering operation takes place on transformed values rather than the original values.

filter A more formal version of %in%, this method returns a filterResult object that can be used in subsequent filter operations as well as providing more metadata about the results of the filtering operation

summarizeFilter When implementing a new filter this method is used to update the filterDetails slot of a filterResult. It is optional and typically only needs to be implemented for data-driven filters.

filterDetails-methods

Obtain details about a filter operation

Description

A filtering operation captures details about its metadata and stores it in a filterDetails slot that is accessed using the filterDetails method. Each set of metadata is indexed by the filterId of the filter allowing for all the metadata in a complex filtering operation to be recovered after the final filtering.

Methods

result = "filterResult", filterId = "missing" When no particular filterId is specified all the details are returned

result = "filterResult", filterId = "ANY" You can also obtain a particular subset of details
**Author(s)**

B. Ellis, P.D. Haaland and N. LeMeur

---

**filter-in-methods**  
*Filter-specific membership methods*

**Description**

Membership methods must be defined for every object of type `filter` with respect to a `flowFrame` object. The operation is considered to be general and may return a logical, numeric or factor vector that will be handled appropriately. The ability to handle logical matrices as well as vectors is also planned but not yet implemented.

**Author(s)**

F. Hahne, B. Ellis

---

**filterResultList-class**  
*Class "filterList"*

**Description**

Container for a list of `filter` objects. The class mainly exists for method dispatch.

**Usage**

```r
filterList(x, filterId=identifier(x[[1]]))
```

**Arguments**

- `x`  
  A list of `filter` objects.

- `filterId`  
  The global identifier of the filter list. As default, we take the filterId of the first `filter` object in `x`.

**Value**

A `filterList` object for the constructor

**Objects from the Class**

Objects are created from regular lists using the constructor `filterList`.

**Slots**

- `.Data`: Object of class "list". The class directly extends `list`, and this slot holds the list data.

- `filterId`: Object of class "character". The identifier for the object.
Extends

Class "list", from data part.

Methods

show signature(object = "filterList"): Print details about the object.

identifier, identifier<- signature(object = "filterList"): Accessor and replacement method for the object’s filterId slot.

Author(s)

Florian Hahne

filter.

Examples

f1 <- rectangleGate(FSC=c(100,200), filterId="testFilter")
f2 <- rectangleGate(FSC=c(200,400))
f1 <- filterList(list(a=f1, b=f2))
f1
identifier(f1)

filter  Filter FCS files

Description

These methods link filter descriptions to a particular set of flow cytometry data allowing for the lightweight calculation of summary statistics common to flow cytometry analysis.

Usage

filter(x,filter,...)

Arguments

x  Object of class flowFrame or flowSet.
filter  An object of class filter or a named list filters.
...  Optional arguments
Details

The **filter** method conceptually links a filter description, represented by a **filter** object, to a particular **flowFrame**. This is accomplished via the **filterResult** object, which tracks the linked frame as well as caching the results of the filtering operation itself, allowing for fast calculation of certain summary statistics such as the percentage of events accepted by the **filter**. This method exists chiefly to allow the calculation of these statistics without the need to first **Subset** a **flowFrame**, which can be quite large.

Value

A **filterResult** object or a list of **filterResult** objects if `x` is a **flowSet**. Note that **filterResult** objects are themselves filters, allowing them to be used in filter expressions or **Subset** operations.

Author(s)

F Hahne, B. Ellis, N. Le Meur

See Also

**filter**, **filterResult**

Examples

```r
samp <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
rectGate <- rectangleGate(filterId="nonDebris","FSC-H"=c(200,Inf))
summary(filter(samp,rectGate))
```

Description

This operator is used to construct a **transformFilter** that first applies a **transformList** to the data before applying the **filter** operation. You may also apply the operator to a **flowFrame** or **flowSet** to obtain transformed values specified in the list.

Author(s)

B. Ellis

Examples

```r
samp <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
plot(transform("FSC-H"=log, "SSC-H"=log) %on% samp)
rectangle <- rectangleGate(filterId="rectangleGateI","FSC-H"=c(4.5, 5.5))
sampFiltered <- filter(samp, rectangle %on% transform("FSC-H"=log, "SSC-H"=log))
res <- Subset(samp, sampFiltered)
plot(transform("FSC-H"=log, "SSC-H"=log) %on% res)
```
filterReference-class

Class filterReference

Description

A reference to another filter inside a reference. Users should generally not be aware that they are using this class, but it is used heavily by "filterSet" classes.

Objects from the Class

Objects are generally not created by users so there is no constructor function.

Slots

name: The R name of the referenced filter
env: The environment where the filter must live
filterId: The filterId, not really used since you always resolve

Extends

Class "filter", directly.

Author(s)

B. Ellis

See Also

"filterSet"

filterResult-class  Class "filterResult"

Description

Container to store the result of applying a filter on a flowFrame object

Slots

frameId: Object of class "character" referencing the flowFrame object filtered. Used for sanity checking.
filterDetails: Object of class "list" describing the filter applied
filterId: Object of class "character" referencing the filter applied
parameters: Object of class "ANY" describing the parameters used to filter the flowFrame

Extends

Class "filter", directly.
filterResultList-class

Methods

== test equality

Author(s)

B. Ellis, N. LeMeur

===

filterResultList-class

Class "filterResultList"

Description

Container to store the result of applying a filter on a flowSet object

Objects from the Class

Objects are created by applying a filter on a flowSet. The user doesn’t have to deal with manual object instantiation.

Slots

.Data: Object of class "list". The class directly extends list, and this slot holds the list data.

frameId: Object of class "character". The IDs of the flowFrames in the filtered flowSet.

filterDetails: Object of class "list". Since filterResultList inherits from filterResult, this slot has to be set. It contains only the input filter.

filterId: Object of class "character". The identifier for the object.

Extends

Methods

[ signature(x = "filterResultList", i = "ANY"): Subset to filterResultList.

[[ signature(x = "filterResultList", i = "ANY"): Subset to individual filterResult.

names signature(x = "filterResultList"): Accessor to the frameId slot.

parameters signature(object = "filterResultList"): Return parameters on which data has been filtered.

show signature(object = "filterResultList"): Print details about the object.
split signature(x = "flowSet", f = "filterResultList"): Split a flowSet based on the results in the filterResultList. See split for details.

summary signature(object = "filterResultList"): Summarize the filtering operation. This creates a filterSummaryList object.

filterSet-class Class filterSet

Description
A container for a collection of related filters.

Objects from the Class
There are several ways to create a filterSet object. There is the filterSet constructor, which creates an empty filterSet object (see the details section for more information). filterSet objects can also be coerced to and from list objects using the as function.

Slots
env: The environment that actually holds the filters
Methods

**names**  An unsorted list of the names of the filters contained within the set.

**sort**  Returns a topological sort of the names of the filters contained within the set. Primarily used by internal functions (such as filter), this method is also useful for planning gating strategy layouts and the like.

**filterReference**  Retrieves references to a filter inside a filterSet

-  Returns the filter reference used inside the filter. See Details.
-  Retrieves the actual filters from a filterSet. Note that composed filters can still contain references.
-  Put a filter into a filterSet. As a convenience, assigning to the """" or NULL name will use the filter's name for assignment. Composed filters can be added easily using formulas rather than attempting to construct filters the long way. The formula interface is also lazy, allowing you to add filters in any order.

Details

**filterSet** objects are intended to provide a convenient grouping mechanism for a particular gating strategy. To accomplish this, much like the **flowSet** object, the **filterSet** object introduces reference semantics through the use of an environment, allowing users to change an upstream filter via the usual assignment mechanism and have that change reflected in all dependent filters. We do this by actually creating two filters for each filter in the **filterSet**. The first is the actual concrete filter, which is assigned to a variable of the form .name where name is the original filter name. A second **filterReference** filter is the created with the original name to point to the internal name. The allows us to evaluate a formula in the environment without creating a copy of the original filter.

B. Ellis

See Also

**filterSet**

Examples

```r
fs = new("filterSet")

## Simple assignment. Note that the filterId slot for the rectangle gate
## is changed.
fs[["filter1"]]) = rectangleGate("FSC-H"=c(.2,.8),"SSC-H"=c(0,.8))

## Convenience assignment using the filterId slot.
fs[[""""]) = norm2Filter("FSC-H", "SSC-H", scale.factor=2, filterId="Live Cells")

## We also support formula interfaces. These two statements are equivalent.
fs["Combined"] = ~ filter1 %subset% `Live Cells`
fs["""] = Combined ~ filter1 %subset% `Live Cells`
fs
as(fs,"list")
as(as(fs,"list"),"filterSet")
```
filterSummary-class

Class "filterSummary"

Description

Class and methods to handle the summary information of a gating operation.

Usage

summary(object, ...)

Arguments

object  
An object inheriting from class filterResult which is to be summarized.

...  
Further arguments that are passed to the generic.

Details

Calling summary on a filterResult object prints summary information on the screen, but also creates objects of class filterSummary for computational access.

Value

An object of class filterSummary for the summary constructor, a named list for the subsetting operators. The $ operator returns a named vector of the respective value, where each named element corresponds to one sub-population.

Objects from the Class

Objects are created by calling summary on a link{filterResult} object. The user doesn’t have to deal with manual object instantiation.

Slots

name: Object of class "character" The name(s) of the populations created in the filtering operation. For a logicalFilterResult this is just a single value; the name of the link{filter}.

ttrue: Object of class "numeric". The number of events within the population(s).

count: Object of class "numeric". The total number of events in the gated flowFrame.

p: Object of class "numeric" The percentage of cells in the population(s).
Methods

```
[[ signature(x = "filterSummary", i = "numeric")]: Subset the filterSummary
to a single population. This only makes sense for multipleFilterResults. The output
is a list of summary statistics.

[[ signature(x = "filterSummary", i = "character")]: see above

$ signature(x = "filterSummary", name = "ANY")]: A list-like accessor to the slots
and more. Valid values are n and count (those are identical), true and in (identical),
false and out (identical), name, p and q(1-p).

coerce signature(from = "filterSummary", to = "data.frame")]: Coerce ob-
ject to data.frame.

length signature(x = "filterSummary")]: The number of populations in the filterSummary.

names signature(x = "filterSummary")]: The names of the populations in the filterSummary.

print signature(x = "filterSummary")]: Print details about the object.

show signature(object = "filterSummary")]: Print details about the object.

toTable signature(x = "filterSummary")]: Coerce object to data.frame.
```

```
Class "filterSummaryList"

Description

Class and methods to handle summary statistics for from filtering operations on whole flowSets.

Arguments

object  An object of class filterResultList which is to be summarized.
... Further arguments that are passed to the generic.

Details

Calling summary on a filterResult object prints summary information on the screen, but also creates objects of class filterSummary for computational access.

Value

An object of class filterSummaryList.

Objects from the Class

Objects are created by calling summary on a link{filterResultList} object. The user doesn’t have to deal with manual object instantiation.

Slots

.Data: Object of class "list". The class directly extends list, and this slot holds the list data.

Extends

Class "list", from data part.

Usage

summary(object, ...)

Methods

toTable signature(x = "filterSummaryList"): Coerce object to data.frame. Additional factors are added to indicate list items in the original object.

### flowFrame-class

#### 'flowFrame': a class for storing observed quantitative properties for a population of cells from a FACS run

#### Description

This class represents the data contained in a FCS file or similar data structure. There are three parts of the data:

1. a numeric matrix of the raw measurement values with rows=events and columns=parameters
2. annotation for the parameters (e.g., the measurement channels, stains, dynamic range)
3. additional annotation provided through keywords in the FCS file

#### Details

Objects of class `flowFrame` can be used to hold arbitrary data of cell populations, acquired in flow-cytometry.

FCS is the Data File Standard for Flow Cytometry, the current version is FCS 3.0. See the vignette of this package for additional information on using the object system for handling of flow-cytometry data.

#### Creating Objects

Objects can be created using

```
new("flowFrame",
  exprs = ...., Object of class matrix
  parameters = ...., Object of class AnnotatedDataFrame
  description = ...., Object of class list
)
```

or the constructor `flowFrame`, with mandatory arguments `exprs` and optional arguments `parameters` and `description`.
flowFrame(exprs, parameters, description=list())

To create a flowFrame directly from an FCS file, use function read.FCS. This is the recommended and safest way of object creation, since read.FCS will perform basic data quality checks upon import. Unless you know exactly what you are doing, creating objects using new or the constructor is discouraged.

Slots

**exprs**: Object of class matrix containing the measured intensities. Rows correspond to cells, columns to the different measurement channels. The colnames attribute of the matrix is supposed to hold the names or identifiers for the channels. The rownames attribute would usually not be set.

**parameters**: An AnnotatedDataFrame containing information about each column of the flowFrame. This will generally be filled in by read.FCS or similar functions using data from the FCS keywords describing the parameters.

**description**: A list containing the meta data included in the FCS file.

Methods

There are separate documentation pages for most of the methods listed here which should be consulted for more details.

Subsetting. Returns an object of class flowFrame. The subsetting is applied to the exprs slot, while the description slot is unchanged. The syntax for subsetting is similar to that of data.frames. In addition to the usual index vectors (integer and logical by position, character by parameter names), flowFrames can be subset via filterResult and filter objects.

*Usage:*

```r
flowFrame[i, j]
flowFrame[filter,]
flowFrame[filterResult,]
```

Note that the value of argument drop is ignored when subsetting flowFrames.

**Subsetting by channel name**. This is similar to subsetting of columns of data.frames, i.e., frame$FSC.H is equivalent to frame[, "FSC.H"]). Note that column names may have to be quoted if they are no valid R symbols (e.g. frame$"FSC-H").

**exprs, exprs<-** Extract or replace the raw data intensities. The replacement value must be a numeric matrix with colnames matching the parameter definitions. Implicit subsetting is allowed (i.e. less columns in the replacement value compared to the original flowFrame, but all have to be defined there).

*Usage:*

```r
exprs(flowFrame)
exprs(flowFrame) <- value
```

**head, tail** Show first/last elements of the raw data matrix

*Usage:*

```r
head(flowFrame)
tail(flowFrame)
```

**description, description<-** Extract or replace the whole list of annotation keywords. Usually one would only be interested in a subset of keywords, in which case the keyword method is more appropriate. The optional hideInternal parameter can be used to exclude internal FCS parameters starting with\$. 
Usage:

description(flowFrame)
description(flowFrame) <- value

keyword, keyword<- Extract one or more entries from the description slot by keyword. Methods are defined for character vectors (select a keyword by name), functions (select a keyword by evaluating a function on their content) and for lists (a combination of the above). See keyword for details.

Usage:

keyword(flowFrame)
keyword(flowFrame, character)
keyword(flowFrame, list)
keyword(flowFrame) <- list(value)

parameters, parameters<- Extract parameters and return an object of class AnnotatedDataFrame, or replace such an object. To access the actual parameter annotation, use pData(parameters(frame)). Replacement is only valid with AnnotatedDataFrames containing all varLabels name, desc, range, minRange and maxRange, and matching entries in the name column to the colnames of the exprs matrix. See parameters for more details.

Usage:

parameters(flowFrame)
parameters(flowFrame) <- value

show Display details about the flowFrame object.

summary Return descriptive statistical summary (min, max, mean and quantile) for each channel

Usage:

summary(flowFrame)

plot Basic plots for flowFrame objects. If the object has only a single parameter this produces a histogram. For exactly two parameters we plot a bivariate density map (see smoothScatter) and for more than two parameters we produce a simple splom plot. To select specific parameters from a flowFrame for plotting, either subset the object or specify the parameters as a character vector in the second argument to plot. The smooth parameters lets you toggle between density-type smoothScatter plots and regular scatterplots. For far more sophisticated plotting of flow cytometry data, see the flowViz package.

Usage:

plot(flowFrame, ...)
plot(flowFrame, character, ...)
plot(flowFrame, smooth=FALSE, ...)

ncol, nrow, dim Extract the dimensions of the data matrix.

Usage:

ncol(flowFrame)
nrow(flowFrame)
dim(flowFrame)

featureNames, colnames, colnames<- Extract parameter names (i.e., the colnames of the data matrix). colnames and featureNames are synonyms. For colnames there is also a replacement method. This will update the name column in the parameters slot as well.

Usage:

featureNames(flowFrame)
colnames(flowFrame)
colnames(flowFrame) <- value
names  Extract pretty formatted names of the parameters including parameter descriptions.
Usage:
  names(flowFrame)

identifier  Extract GUID of a flowFrame. Returns the file name if no GUID is available. See identifier for details.
Usage:
  identifier(flowFrame)

range  Get dynamic range of the flowFrame. Note that this is not necessarily the range of the actual data values, but the theoretical range of values the measurement instrument was able to capture. The values of the dynamic range will be transformed when using the transformation methods for flowFrames. Additional character arguments are evaluated as parameter names for which to return the dynamic range.
Usage:
  range(flowFrame, ...)

each_row, each_col  Apply functions over rows or columns of the data matrix. These are convenience methods. See each_col for details.
Usage:
  each_row(flowFrame, function, ...)
  each_col(flowFrame, function, ...)

transform  Apply a transformation function on a flowFrame object. This uses R’s transform function by treating the flowFrame like a regular data.frame. flowCore provides an additional inline mechanism for transformations (see %on%) which is strictly more limited than the out-of-line transformation described here.
Usage:
  transform(flowFrame, ...)

filter  Apply a filter object on a flowFrame object. This returns an object of class filterResult, which could then be used for subsetting of the data or to calculate summary statistics. See filter for details.
Usage:
  filter(flowFrame, filter)

split  Split flowFrame object according to a filter, a filterResult or a factor. For most types of filters, an optional flowSet=TRUE parameter will create a flowSet rather than a simple list. See split for details.
Usage:
  split(flowFrame, filter, flowSet=FALSE, ...)
  split(flowFrame, filterResult, flowSet=FALSE, ...)
  split(flowFrame, factor, flowSet=FALSE, ...)

Subset  Subset a flowFrame according to a filter or a logical vector. The same can be done using the standard subsetting operator with a filter, filterResult, or a logical vector as first argument.
Usage:
  Subset(flowFrame, filter)
  Subset(flowFrame, logical)

cbind2  Expand a flowFrame by the data in a numeric matrix of the same length. The matrix must have column names different from those of the flowFrame. The additional method for numerics only raises a useful error message.
Usage:
cbind2(flowFrame, matrix)
cbind2(flowFrame, numeric)

**compensate**  Apply a compensation matrix (or a compensation object) on a flowFrame object. This returns a compensated flowFrame.

*Usage:*
compensate(flowFrame, matrix)  compensate(flowFrame, data.frame)

**spillover**  Extract spillover matrix from description slot if present.

*Usage:*
spillover(flowFrame, matrix)

**==**  Test equality between two flowFrames

**<, >, <=, >=**  These operators basically treat the flowFrame as a numeric matrix.

**initialize(flowFrame):**  Object instantiation, used by new; not to be called directly by the user.

**Author(s)**
F. Hahne, B. Ellis, P. Haaland and N. Le Meur

**See Also**
flowSet, read.FCS

**Examples**

```r

---

flowSet-class  

'flowSet': a class for storing flow cytometry raw data from quantitative cell-based assays

---

**Description**

This class is a container for a set of flowFrame objects

**Creating Objects**

Objects can be created using

```r
new('flowSet',
frames = ...., # environment with flowFrames
phenoData = .... # object of class AnnotatedDataFrame
colnames = .... # object of class character
)
```

or via the constructor `flowSet`, which takes arbitrary numbers of flowFrames, either as a list or directly as arguments, along with an optional `AnnotatedDataFrame` for the `phenoData` slot and a character scalar for the name by which the object can be referenced.

`flowSet(...)`, `phenoData`)

Alternatively, flowSets can be coerced from list and environment objects.

`as(list("A"=frameA,"B"=frameB),"flowSet")`

The safest and easiest way to create flowSets directly from FCS files is via the `read.flowSet` function, and there are alternative ways to specify the files to read. See the separate documentation for details.

**Slots**

- **frames**: An environment containing one or more flowFrame objects.
- **phenoData**: A `AnnotatedDataFrame` containing the phenotypic data for the whole data set. Each row corresponds to one of the flowFrames in the frames slot. The sampleNames of phenoData (see below) must match the names of the flowFrame in the frames environment.
colnames: A character object with the (common) column names of all the data matrices in the flowFrames.

Methods

[, [[ Subsetting. \(x[i]\) where \(i\) is a scalar, returns a flowSet object, and \(x[[i]]\) a flowFrame object. In this respect the semantics are similar to the behavior of the subsetting operators for lists. \(x[i, j]\) returns a flowSet for which the parameters of each flowFrame have been subset according to \(j\). \(x[[i, j]]\) returns the subset of a single flowFrame for all parameters in \(j\). Similar to data frames, valid values for \(i\) and \(j\) are logicals, integers and characters.

Usage:
flowSet[i]
flowSet[i,j]
flowSet[[i]]

$ Subsetting by frame name. This will return a single flowFrame object. Note that names may have to be quoted if they are no valid R symbols (e.g. flowSet$"sample 1"

colnames, colnames<- Extract or replace the colnames slot.

Usage:
colnames(flowSet)
colnames(flowSet) <- value

identifier, identifier<- Extract or replace the name item from the environment.

Usage:
identifier(flowSet)
identifier(flowSet) <- value

phenoData, phenoData<- Extract or replace the AnnotatedDataFrame from the phenoData slot.

Usage:
phenoData(flowSet)
phenoData(flowSet) <- value

pData, pData<- Extract or replace the data frame (or columns thereof) containing actual phenotypic information from the phenoData slot.

Usage:
pData(flowSet)
pData(flowSet)$someColumn <- value

varLabels, varLabels<- Extract and set varLabels in the AnnotatedDataFrame of the phenoData slot.

Usage:
varLabels(flowSet)
varLabels(flowSet) <- value

sampleNames Extract and replace sample names from the phenoData object. Sample names correspond to frame identifiers, and replacing them will also replace the GUID slot for each frame. Note that sampleName need to be unique.

Usage:
sampleNames(flowSet)
sampleNames(flowSet) <- value
**keyword**  Extract or replace keywords specified in a character vector or a list from the description slot of each frame. See `keyword` for details.

*Usage:*

```r
keyword(flowSet, list(keywords))  
keyword(flowSet, keywords)  
keyword(flowSet) <- list(foo="bar")
```

**length**  number of `flowFrame` objects in the set.

*Usage:*

```r
length(flowSet)
```

**show**  display object summary.

**summary**  Return descriptive statistical summary (min, max, mean and quantile) for each channel of each `flowFrame`

*Usage:*

```r
summary(flowSet)
```

**fsApply**  Apply a function on all frames in a `flowSet` object. Similar to `sapply`, but with additional parameters. See separate documentation for details.

*Usage:*

```r
fsApply(flowSet, function, ...)  
fsApply(flowSet, function, use.exprs=TRUE, ...)
```

**compensate**  Apply a compensation matrix on all frames in a `flowSet` object. See separate documentation for details.

*Usage:*

```r
compensate(flowSet, matrix)
```

**transform**  Apply a transformation function on all frames of a `flowSet` object. See separate documentation for details.

*Usage:*

```r
transform(flowSet, ...)
```

**filter**  Apply a filter object on a `flowSet` object. There are methods for `filters`, `filterSets` and lists of filters. The latter has to be a named list, where names of the list items are matching sampleNames of the `flowSet`. See `filter` for details.

*Usage:*

```r
filter(flowSet, filter)  
filter(flowSet, list(filters))
```

**split**  Split all `flowSet` objects according to a `filter`, `filterResult` or a list of such objects, where the length of the list has to be the same as the length of the `flowSet`. This returns a list of `flowFrames` or an object of class `flowSet` if the `flowSet` argument is set to `TRUE`. Alternatively, a `flowSet` can be split into separate subsets according to a factor (or any vector that can be coerced into factors), similar to the behaviour of `split` for lists. This will return a list of `flowSets`. See `split` for details.

*Usage:*

```r
split(flowSet, filter)  
split(flowSet, filterResult)  
split(flowSet, list(filters))  
split(flowSet, factor)
```
**Subset** Returns a flowSet of flowFrames that have been subset according to a filter or filterResult, or according to a list of such items of equal length as the flowSet.

*Usage:*

Subset(flowSet, filter)
Subset(flowSet, filterResult)
Subset(flowSet, list(filters))

**rbind2** Combine two flowSet objects, or one flowSet and one flowFrame object.

*Usage:*

rbind2(flowSet, flowSet)
rbind2(flowSet, flowFrame)

**spillover** Compute spillover matrix from a compensation set. See separate documentation for details.

**Important note on storage and performance**

The bulk of the data in a flowSet object is stored in an environment, and is therefore not automatically copied when the flowSet object is copied. If x is an object of class flowSet, then the code

y <- x

will create an object y that contains copies of the phenoData and administrative data in x, but refers to the same environment with the actual fluorescence data. See below for how to create proper copies.

The reason for this is performance. The pass-by-value semantics of function calls in R can result in numerous copies of the same data object being made in the course of a series of nested function calls. If the data object is large, this can result in considerable cost of memory and performance. flowSet objects are intended to contain experimental data in the order of hundreds of Megabytes, which can effectively be treated as read-only: typical tasks are the extraction of subsets and the calculation of summary statistics. This is afforded by the design of the flowSet class: an object of that class contains a phenoData slot, some administrative information, and a reference to an environment with the fluorescence data; when it is copied, only the reference is copied, but not the potentially large set of fluorescence data themselves.

However, note that subsetting operations, such as y <- x[i] do create proper copies, including a copy of the appropriate part of the fluorescence data, as it should be expected. Thus, to make a proper copy of a flowSet x, use y <- x[seq(along=x)]

### fsApply

**fsApply**

**Apply a Function over values in a flowSet**

**Description**

`fsApply` like many of the `apply`-style functions in R acts as an iterator for `flowSet` objects, allowing the application of a function to either the `flowFrame` or the data matrix itself. The output can be reconstructed as either a `flowSet`, a list or a matrix depending on options and the type of objects returned.

**Usage**

```r
fsApply(x, FUN, ..., simplify=TRUE, use.expr=FALSE)
```

**Arguments**

- **x**
  - `flowSet` to be used
- **FUN**
  - the function to be applied to each element of `x`
- **simplify**
  - logical (default: `TRUE`); if all true and all objects are `flowFrame` objects, a `flowSet` object will be constructed. If all of the values are of the same type there will be an attempt to construct a vector or matrix of the appropriate type (e.g. all numeric results will return a matrix).
gateActionItem-class

```R
use.exprs logical (default: FALSE); should the FUN be applied on the flowFrame object or the expression values.
...
optional arguments to FUN.
```

apply, sapply

Examples

```R
fcs.loc <- system.file("extdata", package="flowCore")
file.location <- paste(fcs.loc, dir(fcs.loc), sep="/"
samp <- read.flowSet(file.location[1:3])

# Get summary information about each sample.
fsApply(samp, summary)

# Obtain the median of each parameter in each frame.
fsApply(samp, each_col, median)
```

---

gateActionItem-class

Class "gateActionItem"

Description

Class and method to capture gating operations in a flow cytometry workflow.

Usage

```R
gateActionItem(ID = paste("gateActionRef", guid(), sep = "_"), name = paste("action", identifier(get(gate)), sep = "_"), parentView, gate, filterResult, workflow)
```

Arguments

- **workflow**: An object of class `workFlow` for which a view is to be created.
- **ID**: A unique identifier of the view, most likely created by using the internal `guid` function.
- **name**: A more human-readable name of the view.
- **parentView, gate, filterResult**: References to the parent `view`, `filter`, and `filterResult` objects, respectively.
Details

gateActionItems provide a means to bind gating operations in a workflow. Each gateActionItem represents a single filter.

Value

A reference to the gateActionItem that is created inside the workflow environment as a side effect of calling the add method. A gateActionItem object for the constructor.

Objects from the Class

Objects should be created using the add method, which creates a gateActionItem from a filter object and directly assigns it to a workflow. Alternatively, one can use the gateActionItem constructor function for more programmatic access.

Slots

gate: Object of class "fcFilterReference". A reference to the filter that is used for the gating operation.

filterResult: Object of class "fcFilterResultReference". A reference to the filterResult produced by the gating operation.

ID: Object of class "character". A unique identifier for the actionItem.

name: Object of class "character". A more human-readable name

parentView: Object of class "fcViewReference". A reference to the parent view the gateActionItem is applied on.

env: Object of class "environment". The evaluation environment in the workflow.

Extends

Class "actionItem", directly.

Methods

gate signature(object = "gateActionItem"): Accessor to the gate slot. Note that this resolved the reference, i.e., the filter object is returned.

print signature(x = "gateActionItem"): Print details about the object.

Rm signature(symbol = "gateActionItem", envir = "workflow", subSymbol = "character"): Remove a gateActionItem from a workflow. This method is recursive and will also remove all dependent views and actionItems.

show signature(object = "gateActionItem"): Print details about the object.

summary signature(object = "gateActionItem"): Summarize the gating operation and return the appropriate filterSummary object.

Examples

showClass("view")

gateView-class  Class "gateView"

Description

Class and method to capture the result of gating operations in a flow cytometry workflow.

Usage

gateView(workflow, ID=paste("gateViewRef", guid(), sep="_"),
name="default", action, data, indices,
filterResult, frEntry)

Arguments

workflow  An object of class workFlow for which a view is to be created.
ID  A unique identifier of the view, most likely created by using the internal guid function.
name  A more human-readable name of the view.
data, action, filterResult  References to the data, filterResult, and actionItem objects, respectively.
indices  A logical vector of indices in the parent data.
frEntry  A character vector indicating the name of the population in the filterResult.

Details

gateViews provide a means to bind the results of gating operations in a workflow. Each gateView represents one of the populations that arise from the gating. logicalFilterResults create two gateViews (events in the gate and events not in the gate), multipleFilterResults one view for each population. See the documentation of the parent class view for more details.

Value

A reference to the gateView that is created inside the workFlow environment as a side effect of calling the add method.

A gateView object for the constructor.

Objects from the Class

Objects should be created using the add method, which creates a gateView from a filter object and directly assigns it to a workFlow. Alternatively, one can use the gateView constructor function for more programmatic access.
Slots

- **indices**: Object of class "logical". The indices in the parent data for events that are within the filter.
- **filterResult**: Object of class "fcFilterResultReference". A reference to the outcome of the filtering operation.
- **frEntry**: Object of class "character". The population in the filterResult that corresponds to the current view. See details for further explanation.
- **ID**: Object of class "character". A unique identifier for the view.
- **name**: Object of class "character". A more human-readable name
- **action**: Object of class "fcActionReference". A reference to the actionItem that generated the view.
- **env**: Object of class "environment". The evaluation environment in the workFlow.
- **data**: Object of class "fcDataReference". A reference to the data that is associated to the view. Subsets of the data are only generated when a further action is invoked on a particular gateView. Summary statistics about the view can be acquired through the usual process of summarizing filterResults.

Extends

Class "view", directly.

Methods

- **Rm** signature(symbol = "gateView", envir = "workFlow", subSymbol = "character"):
  Remove a gateView from a workFlow. This method is recursive and will also remove all dependent views and actionItems.

- **summary** signature(x = "formula", data = "gateView"):
  Summarize the gating operation.

- **xyplot** signature(x = "formula", data = "gateView"):
  Plot the data of the gateView along with the gate.

Extract of a Graft versus Host Disease monitoring experiment (Rizzieri et al., 2007)

Description

A flow cytometry high throughput screening was used to identify biomarkers that would predict the development of GvHD. The GvHD dataset is an extract of a collection of weekly peripheral blood samples obtained from patients following allogenic blood and marrow transplant. Samples were taken at various time points before and after graft.

Usage

data(GvHD)

Format

The format is an object of class flowSet composed of 35 flowFrames. Each flowFrame corresponds to one sample at one time point. The phenodata lists:

- **Patient**  The patient Id code
- **Visit**    The number of visits to the hospital
- **Days**    The number of days since the graft. Negative values correspond to days before the graft.
- **Grade**  Grade of the cancer

Details

This GvHD dataset represents the measurements of one biomarker (leukocyte) for 5 patients over 7 visits (7 time points). The blood samples were labeled with four different fluorescent probes to identify the biomarker and the fluorescent intensity was determined for at least ten thousand cells per sample.

Source

Complete dataset available at [http://www.ficcs.org/software.html#Data_Files](http://www.ficcs.org/software.html#Data_Files), the Flow Informatics and Computational Cytometry Society website (FICCS)

References

Description

Hyperlog transformation of a parameter is defined by the function

\[ f(\text{parameter}, a, b) = \text{rootEH}(y, a, b) - \text{parameter} \]

where \( \text{EH} \) is a function defined by

\[
\text{EH}(y, a, b) = 10^{\left(\frac{y}{a}\right)} + \frac{b \cdot y}{a} - 1 \quad y \geq 0 \\
-10^{-\left(\frac{y}{a}\right)} + \frac{b \cdot y}{a} + 1 \quad y < 0
\]

Objects from the Class

Objects can be created by calls to the constructor `hyperlog(parameter, a, b, transformationId)`

Slots

- **Data**: Object of class "function" ~~
- **a**: Object of class "numeric" - numeric constant greater than zero
- **b**: Object of class "numeric" numeric constant greater than zero
- **parameters**: Object of class "transformation" - flow parameter to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation

Extends

Methods

No methods defined with class "hyperlog" in the signature.

Note

The transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

See Also
EHtrans

Examples

```r
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
hlog1<-hyperlog("FSC-H",a=1,b=1,transformationId="hlog1")
transOut<-eval(hlog1)(exprs(dat))
```

identifier Retrieve the GUID of flowCore objects

Description
Retrieve the GUID (globally unique identifier) of a `flowFrame` that was generated by the cytometer or the identifier of a `filter` or `filterResult` given by the analyst.

Usage

```r
identifier(object)
```

Arguments

object Object of class `flowFrame`, `filter` or `filterResult`.

Details
GUID or Globally Unique Identifier is a pseudo-random number used in software applications. While each generated GUID is not guaranteed to be unique, the total number of unique keys ($2^{128}$) is so large that the probability of the same number being generated twice is very small.

Note that if no GUID has been recorded along with the FCS file, the name of the file is returned.

Value
Character vector representing the GUID or the name of the file.

Methods

```r
object = "filter" Return identifier of a `filter` object.
object = "filterReference" Return identifier of a `filterReference` object.
object = "filterResult" Return identifier of a `filterResult` object.
object = "transform" Return identifier of a `transform` object.
object = "flowFrame" Return GUID from the description slot of a `flowFrame` object or, alternatively, the name of the input FCS file in case none can be found. For `flowFrame` objects there also exists a replacement method.
```
In the `invsplitscale-class`, the inverse split scale transformation is defined by the function:

\[
f(\text{parameter}, r, \text{maxValue}, \text{transitionChannel}) = \begin{cases} 
\frac{\text{parameter} - b}{a} & \text{parameter} \leq t \cdot a + b \\
\frac{10^\text{parameter \cdot r}}{c} & \text{parameter} > t \cdot a + b
\end{cases}
\]

where,

\[
b = \frac{\text{transitionChannel}}{2}
\]

\[
d = \frac{2 \cdot \log_{10}(e) \cdot r}{\text{transitionChannel}} + \log_{10}(\text{maxValue})
\]

\[
t = 10^{\log_{10} t}
\]

\[
a = \frac{\text{transitionChannel}}{2 \cdot t}
\]

\[
\log_{10} c = \frac{(a \cdot t + b) \cdot d}{r}
\]

Objects from the Class

Objects can be created by calls to the constructor `invsplitscale(parameters, r, maxValue, transitionChannel, transformationId)`.

Slots

- **Data**: Object of class "function" -
- **r**: Object of class "numeric" - a positive value indicating the range of the logarithmical part of the display
- **maxValue**: Object of class "numeric" - a positive value indicating the maximum value the transformation is applied to
- **transitionChannel**: Object of class "numeric" - non-negative value that indicates where to split the linear vs. logarithmical transformation
- **parameters**: Object of class "transformation" - flow parameter to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation
Extends

Methods

No methods defined with class "invsplitscale" in the signature.

Note

The transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

Author(s)

Gopalakrishnan N,F.Hahne

splitscale

Examples

dat <- read.FCS(system.file("extdata","0877408774.B08",package="flowCore"))
spl1<-invsplitscale("FSC-H",r=512,maxValue=2000,transitionChannel=512)
transOut<-eval(spl1)(exprs(dat))

Description

Accessor and replacement methods for items in the description slot (usually read in from a FCS file header). It lists the keywords and its values for a flowFrame specified by a character vector. Additional methods for function and lists exists for more programmatic access to the keywords.

Usage

keyword(object, keyword)

Arguments

object Object of class flowFrame.
keyword Character vector or list of potential keywords or function. If missing all keywords are returned.
The **keyword** methods allow access to the keywords stored in the FCS files, either for a `flowFrame` or for a list of frames in a `flowSet`. The most simple use case is to provide a character vector or a list of character strings of keyword names. A more sophisticated version is to provide a function which has to take one mandatory argument, the value of this is the `flowFrame`. This can be used to query arbitrary information from the `flowFrames description` slot or even the raw data. The function has to return a single character string. The **list** methods allow to combine functional and direct keyword access. The replacement method takes a named character vector or a named list as input. R’s usual recycling rules apply when replacing keywords for a whole `flowSet`

### Methods

- **object = "flowFrame", keyword = "character"**  
  Return values for all keywords from the `description` slot in `object` that match the character vector `keyword`.

- **object = "flowFrame", keyword = "function"**  
  Apply the function in `keyword` on the `flowFrame object`. The function needs to be able to cope with a single argument and it needs to return a single character string. A typical use case is for instance to paste together values from several different keywords or to compute some statistic on the `flowFrame` and combine it with one or several other keywords.

- **object = "flowFrame", keyword = "list"**  
  Combine characters and functions in a list to select keyword values.

- **object = "flowFrame", keyword = "missing"**  
  This is essentially an alias for `description` and returns all keyword-value pairs.

- **object = "flowSet", keyword = "list"**  
  This is a wrapper around `fsApply(object, keyword, keyword)` which essentially iterates over the frames in the `flowSet`.

- **object = "flowSet", keyword = "ANY"**  
  This first coerces the `keyword` (mostly a character vector) to a list and then calls the next applicable method.

### Examples

```r
samp <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
keyword(samp)
keyword(samp, "FCSversion")
keyword(samp, function(x,...) paste(keyword(x, "SAMPLE ID"), keyword(x, "GUID"), sep="_"))
keyword(samp) <- list(foo="bar")
data(GvHD)
keyword(GvHD, list("GUID", cellnumber=function(x) nrow(x)))
keyword(GvHD) <- list(sample=sampleNames(GvHD))
```
Description

A filter that performs one-dimensional k-means (Lloyd-Max) clustering on a single flow parameter.

Usage

kmeansFilter(..., filterId="defaultKmeansFilter")

Arguments

... kmeansFilter are defined by a single flow parameter and an associated list of k population names. They can be given as a character vector via a named argument, or as a list with a single named argument. In both cases the name will be used as the flow parameter and the content of the list or of the argument will be used as population names, after coercing to character. For example

kmeansFilter(FSC=c("a", "b", "c"))

or

kmeansFilter(list(SSC=1:3))

If the parameter is not fully realized, but instead is the result of a transformation operation, two arguments need to be passed to the constructor: the first one being the transform object and the second being a vector of population names which can be coerced to a character. For example

kmeansFilter(tf, c("D", "E"))

filterId An optional parameter that sets the filterId of the object. The filter can later be identified by this name.

Details

The one-dimensional k-means filter is a multiple population filter capable of operating on a single flow parameter. It takes a parameter argument associated with two or more populations and results in the generation of an object of class multipleFilterResult. Populations are considered to be ordered such that the population with the smallest mean intensity will be the first population in the list and the population with the highest mean intensity will be the last population listed.

Value

Returns a kmeansFilter object for use in filtering flowFrames or other flow cytometry objects.

Extends

Class parameterFilter, directly.
Class concreteFilter, by class parameterFilter, distance 2.
Class filter, by class parameterFilter, distance 3.
kmeansFilter-class

Slots

- **populations**: Object of class `character`. The names of the \( k \) populations (or clusters) that will be created by the `kmeansFilter`. These names will later be used for the respective subpopulations in `split` operations and for the summary of the `filterResult`.

- **parameters**: Object of class `parameters`, defining a single parameter for which the data in the `flowFrame` is to be clustered. This may also be a `transformation` object.

- **filterId**: Object of class `character`, an identifier or name to reference the `kmeansFilter` object later on.

Objects from the Class

Like all other `filter` objects in `flowCore`, `kmeansFilter` objects should be instantiated through their constructor `kmeansFilter()`. See the Usage section for details.

Methods

- `%in%` signature(`x = "flowFrame", table = "kmeansFilter"`): The workhorse used to evaluate the filter on data.

  **Usage:**
  
  This is usually not called directly by the user, but internally by the `filter` methods.

- `show` signature(`object = "kmeansFilter"`): Print information about the filter.

  **Usage:**
  
  The method is called automatically whenever the object is printed on the screen.

Note

See the documentation in the `flowViz` package for plotting of `kmeansFilters`.

Examples

```r
## Loading example data
dat <- read.FCS(system.file("extdata","0877408774.B08",
package="flowCore"))

## Create the filter
kf <- kmeansFilter("FSC-H"=c("Pop1","Pop2","Pop3"), filterId="myKmFilter")

## Filtering using kmeansFilters
fres <- filter(dat, kf)
fres
summary(fres)
names(fres)

## The result of quadGate filtering are multiple sub-populations
```
## and we can split our data set accordingly
split(dat, fres)

## We can limit the splitting to one or several sub-populations
split(dat, fres, population="Pop1")
split(dat, fres, population=list(keep=c("Pop1","Pop2")))

### linearTransform

Create the definition of a linear transformation function to be applied on a data set

#### Description

Create the definition of the linear transformation that will be applied on some parameter via the `transform` method. The definition of this function is currently \( x \leftarrow a \cdot x + b \)

#### Usage

```r
linearTransform(transformationId="defaultLinearTransform", a = 1, b = 0)
```

#### Arguments

- `transformationId`  
  character string to identify the transformation
- `a`  
  double that corresponds to the multiplicative factor in the equation
- `b`  
  double that corresponds to the additive factor in the equation

#### Value

Returns an object of class `transform`.

#### Author(s)

N. LeMeur

#### See Also

`transform-class`, `transform`

#### Examples

```r
samp <- read.FCS(system.file("extdata",  
                          "0877408774.B08", package="flowCore"))
linearTrans <- linearTransform(transformationId="Linear-transformation", a=2, b=0)
dataTransform <- transform(samp, `FSC-H`=linearTrans(`FSC-H`))
```
Create the definition of a ln transformation function (natural logarithm) to be applied on a data set

Description

Create the definition of the ln Transformation that will be applied on some parameter via the transform method. The definition of this function is currently x<-log(x)*(r/d). The transformation would normally be used to convert to a linear valued parameter to the natural logarithm scale. Typically r and d are both equal to 1.0. Both must be positive.

Usage

lnTransform(transformationId="defaultLnTransform", r=1, d=1)

Arguments

transformationId
  character string to identify the transformation
r
  positive double that corresponds to a scale factor.
d
  positive double that corresponds to a scale factor

Value

Returns an object of class transform.

plot(density(exprs(GvHD[[1]])[ ,1]), main="Original")
plot(density(exprs(ln1[[1]])[ ,1]), main="Ln Transform")
**logarithm-class**  

**Class “logarithm”**

**Description**

Logarithmic transformation of an argument is a transformation defined by the function

\[ f(\text{parameter}, a, b) = \ln(a * \text{parameter}) * b \quad a * \text{parameter} > 0 \]

\[ 0 \quad a * \text{parameter} \leq 0 \]

**Objects from the Class**

Objects can be created by calls to the constructor `logarithm(parameters,a,b,transformationId)`

**Slots**

- **Data**: Object of class "function" ~
- **a**: Object of class "numeric" - non zero multiplicative constant
- **b**: Object of class "numeric" - non zero multiplicative constant
- **parameters**: Object of class "transformation" - flow parameters to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation

**Extends**

**Methods**

No methods defined with class "logarithm" in the signature.

**Note**

The logarithm transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

logicleTransform  

*Compute a transform using the 'logicle' function*

**Description**

Logicle transformation create a subset of biexponentialTransform

**Usage**

```r
logicleTransform(transformationId="defaultLogicleTransform", w = 0, r = 262144, d = 5, tol = .Machine$double.eps^0.8, maxit = as.integer(5000))
```

**Arguments**

- `transformationId`: A name to assign to the transformation. Used by the transform/filter integration routines.
- `w`: positive number that corresponds to the width of the negative data range and the range of linearized data in natural log
- `r`: top of the scale data value, e.g. 10000 for common 4 decade data or 262144 for a 18 bit data range.
- `d`: breath of the display in natural logarithm units.
- `tol`: Acceptable tolerance of the root value
- `maxit`: Maximum iterations allowed for the root search process

samp <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))
samp <- GvHD[[1]]
logicle <- logicleTransform(w=2, "logicle")
after <- transform(samp, "FSC-H"-logicle(\"FSC-H\"))
```
logTransform

Create the definition of a log transformation function (base specified by user) to be applied on a data set

Description

Create the definition of the log Transformation that will be applied on some parameter via the transform method. The definition of this function is currently x<-log(x,logbase)*(r/d). The transformation would normally be used to convert to a linear valued parameter to the natural logarithm scale. Typically r and d are both equal to 1.0. Both must be positive. logbase = 10 corresponds to base 10 logarithm.

Usage

logTransform(transformationId="defaultLogTransform", logbase=10, r=1, d=1)

Arguments

transformationId
character string to identify the transformation

logbase
positive double that correponds to the base of the logarithm.

r
positive double that correponds to a scale factor.

d
positive double that correponds to a scale factor

Value

Returns an object of class transform.

dataTransform <- transform(samp,`FSC-H`=logTrans(`FSC-H`))
manyFilterResult-class

Class "manyFilterResult"

Description

The result of a several related, but possibly overlapping filter results. The usual creator of this object will usually be a filter operation of filterSet object on a flowFrame object.

Slots

subSet: Object of class "matrix"
frameId: Object of class "character" referencing the flowFrame object filtered. Used for sanity checking.
filterDetails: Object of class "list" describing the filter applied
filterId: Object of class "character" referencing the filter applied

Extends

Class "filterResult", directly. Class "filter", by class "filterResult", distance 2.

Methods

[, [[ subsetting. If x is manyFilterResult, then x[[i]] a FilterResult object. The semantics is similar to the behavior of the subsetting operators for lists.
length number of filterResult objects in the set.
names names of the filterResult objects in the set.
summary summary filterResult objects in the set.

Author(s)

B. Ellis

FilterResult

Examples

showClass("multipleFilterResult")
norm2Filter-class

Class "norm2Filter"

Description
Class and constructors for a filter that fits a bivariate normal distribution to a data set of paired values and selects data points according to their standard deviation from the fitted distribution.

Usage

```
norm2Filter(x, y, method="covMcd", scale.factor=1, n=50000, filterId="defaultNorm2Filter")
```

Arguments

- `x, y`: Characters giving the names of the measurement parameter on which the filter is supposed to work on. `y` can be missing in which case `x` is expected to be a character vector of length 2 or a list of characters.
- `filterId`: An optional parameter that sets the filterId slot of this filter. The object can later be identified by this name.
- `scale.factor, n`: Numerics of length 1, used to set the scale.factor and n slots of the object.
- `method`: Character in `covMcd` or `cov.rob`, used to set the method slot of the object.

Details
The filter fits a bivariate normal distribution to the data and selects all events within the Mahalanobis distance multiplied by the scale.factor argument. The constructor `norm2Filter` is a convenience function for object instantiation. Evaluating a `curv2Filter` results in an object of class `logicalFilterResult`. Accordingly, `norm2Filters` can be used to subset and to split flow cytometry data sets.

Value
Returns a `norm2Filter` object for use in filtering `flowFrames` or other flow cytometry objects.

Extends
Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots
- `method`: One of `covMcd` or `cov.rob` defining method used for computation of covariance matrix.
- `scale.factor`: Numeric vector giving factor of standard deviations used for data selection (all points within scalefac standard deviations are selected).
**transformation**: Object of class "list" containing `transform` objects, if applicable they are applied to the data before filtering.

**n**: Object of class "numeric", the number of events used to compute the covariance matrix of the bivariate distribution.

**filterId**: Object of class "character" referencing the filter.

**parameters**: Object of class "ANY" describing the parameters used to filter the `flowFrame` or `flowSet`.

**Objects from the Class**

Objects can be created by calls of the form `new("norm2Filter", ...)` or using the constructor `norm2Filter`. The constructor is the recommended way of object instantiation:

**Methods**

- `%in%` signature(x = "flowFrame", table = "norm2Filter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.

- `show` signature(object = "norm2Filter"): Print information about the filter.

**Note**

See the documentation in the `flowViz` package for plotting of `norm2Filters`.

**Author(s)**

F. Hahne

**See Also**

- `cov.rob`, `covMcd`, `filter` for evaluation of `norm2Filters` and `split` and `Subset` for splitting and subsetting of flow cytometry data sets based on that.

**Examples**

```r
## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Create directly. Most likely from a command line
norm2Filter("FSC-H", "SSC-H", filterId="myCurv2Filter")

## To facilitate programmatic construction we also have the following
n2f <- norm2Filter(filterId="myNorm2Filter", x=list("FSC-H", "SSC-H"), scale.factor=2)
n2f <- norm2Filter(filterId="myNorm2Filter", x=c("FSC-H", "SSC-H"), scale.factor=2)

## Filtering using norm2Filter
fres <- filter(dat, n2f)
fres
summary(fres)
```
## The result of norm2 filtering is a logical subset
Subset(dat, fres)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
split(dat, fres)

---

### normalization-class

**Class** "normalization"

#### Description

Class and methods to normalize a flowSet using a potentially complex normalization function.

#### Usage

```r
normalization(parameters, normalizationId="defaultNormalization", normFunction, arguments=list())
```

```r
normalize(data, x)
```

#### Arguments

- `parameters` Character vector of parameter names.
- `normalizationId` The identifier for the normalization object.
- `x` An object of class `flowSet`.
- `normFunction` The normalization function
- `arguments` The list of additional arguments to `normFunction`
- `data` The `flowSet` to normalize.

#### Details

Data normalization of a flowSet is a rather fuzzy concept and the class mainly existst for method dispatch in the workflow tools. The idea is to have a rather general function that takes a flowSet and a list of parameter names as input and applies any kind of normalization to the respective data columns. The output of the function has to be a flowSet again. Although we don’t formally check for it, the dimensions of the input and of the output set should remain the same. Additional arguments may be passed to the normalization function via the arguments list. Internally we evaluate the function using `do.call` and one should check its documentation for details.

Currently, the most prominent example for a normalization function is warping, as provided by the flowStats package.

#### Value

- A normalization object for the constructor.
- A `flowSet` for the `normalize` methods.
Objects from the Class

Objects should be created using the constructor `normalize()`. See the Usage and Arguments sections for details.

Slots

- **parameters**: Object of class "character". The flow parameters that are supposed to be normalized by the normalization function.
- **normalizationId**: Object of class "character". An identifier for the object.
- **normFunction**: Object of class "function". The normalization function. It has to take two mandatory arguments: `x`, the `flowSet`, and `parameters`, a character of parameter names that are to be normalized by the function. Additional arguments have to be passed in via `arguments`.
- **arguments**: Object of class "list". A names list of additional arguments. Can be NULL.

Methods

- `add` signature `signature(wf = "workFlow", action = "normalization")`: The constructor for the workFlow.
- `identifier<-` signature `signature(object = "normalization", value = "character")`: Set method for the identifier slot.
- `identifier` signature `signature(object = "normalization")`: Get method for the identifier slot.
- `normalize` signature `signature(data = "flowSet", x = "normalization")`: Apply a normalization to a `flowSet`.
- `parameters` signature `signature(object = "normalization")`: The more generic constructor.

**normalizeActionItem-class**

*Class "normalizeActionItem"*

Description

Class and method to capture normalization operations in a flow cytometry workflow.

Usage

```r
normalizeActionItem(ID = paste("normActionRef", guid(), sep = "_"),
                    name = paste("action", identifier(get(normalization)), sep = "_"),
                    parentView, normalization, workflow)
```
**normalizeActionItem-class**

**Arguments**

- **workflow**: An object of class `workFlow` for which a view is to be created.
- **ID**: A unique identifier of the view, most likely created by using the internal `guid` function.
- **name**: A more human-readable name of the view.
- **parentView, normalization**: References to the parent `view` and `normalization` objects, respectively.

**Details**

`normalizeActionItems` provide a means to bind normalization operations like warping in a `workflow`. Each `normalizeActionItem` represents a single `normalization`.

**Value**

A reference to the `normalizeActionItem` that is created inside the `workFlow` environment as a side effect of calling the `add` method.

A `normalizeActionItem` object for the constructor.

**Objects from the Class**

Objects should be created using the `add` method, which creates a `normalizeActionItem` from a `normalization` object and directly assigns it to a `workFlow`. Alternatively, one can use the `normalizeActionItem` constructor function for more programmatic access.

**Slots**

- **normalization**: Object of class "fcNormalizationReference". A reference to the `normalization` object that is used for the compensation operation.
- **ID**: Object of class "character". A unique identifier for the `actionItem`.
- **name**: Object of class "character". A more human-readable name
- **parentView**: Object of class "fcViewReference". A reference to the parent `view` the `normalizeActionItem` is applied on.
- **env**: Object of class "environment". The evaluation environment in the `workFlow`.

**Extends**

Class "`actionItem`", directly.

**Methods**

- `print` signature(`x = "normalizeActionItem"`): Print details about the object.
- `Rm` signature(`symbol = "normalizeActionItem", envir = "workFlow", subSymbol = "character"`): Remove a `normalizeActionItem` from a `workFlow`. This method is recursive and will also remove all dependent `views` and `actionItems`.
- `show` signature(`object = "normalizeActionItem"`): Print details about the object.

**Author(s)**

Florian Hahne
normalizeView-class

normalizeView-class

Class “normalizeView”

Description

Class and method to capture the result of normalization operations in a flow cytometry workflow.

Usage

```
normalizeView(workflow, ID=paste("normViewRef", guid(), sep="_"),
              name="default", action, data)
```

Arguments

- **workflow**: An object of class `workFlow` for which a view is to be created.
- **ID**: A unique identifier of the view, most likely created by using the internal `guid` function.
- **name**: A more human-readable name of the view.
- **data, action**: References to the data and `actionItem` objects, respectively.

Value

A reference to the `normalizeView` that is created inside the `workFlow` environment as a side effect of calling the `add` method.

A `normalizeView` object for the constructor.

Objects from the Class

Objects should be created using the `add` method, which creates a `normalizeView` from a `normalization` object and directly assigns it to a `workFlow`. Alternatively, one can use the `normalizeView` constructor function for more programmatic access.

Slots

- **ID**: Object of class "character". A unique identifier for the view.
- **name**: Object of class "character". A more human-readable name
- **action**: Object of class "fcActionReference". A reference to the `actionItem` that generated the view.
- **env**: Object of class "environment". The evaluation environment in the `workFlow`.
- **data**: Object of class "fcDataReference". A reference to the data that is associated to the view.
**parameterFilter-class**

**Extends**

Class "view", directly.

**Methods**

**Rm** signature(symbol = "normalizeView", envir = "workFlow", subSymbol = "character"): Remove a normalizeView from a workFlow. This method is recursive and will also remove all dependent views and actionItems.

**parameterFilter-class**

*Class "parameterFilter"*

**Description**

A concrete filter that acts on a set of parameters.

**Objects from the Class**

parameterFilter objects are never created directly. This class serves as an inheritance point for filters that depends on particular parameters.

**Slots**

- **parameters**: The names of the parameters employed by this filter
- **filterId**: The filter identifier

**Extends**

Class "concreteFilter", directly. Class "filter", by class "concreteFilter", distance 2.

**Methods**

No methods defined with class "parameterFilter" in the signature.

**Author(s)**

B. Ellis
parameters-class  Class "parameters"

Description
A representation of flow parameters that allows for referencing.

Objects from the Class
Objects will be created internally whenever necessary and this should not be of any concern to the user.

Slots
.Data: A list of the individual parameters

Extends
Class "list", from data part. Class "vector", by class "list", distance 2.

Methods
No methods defined with class "parameters" in the signature.

Author(s)
Nishant Gopalakrishnan

parameters  Obtain information about parameters for flow cytometry objects.

Description
Many different objects in flowCore are associated with one or more parameters. This includes filter, flowFrame and parameterFilter objects that all either describe or use parameters.

Usage
parameters(object, ...)

Arguments
object  Object of class filter, flowFrame or parameterFilter.
...  Further arguments that get passed on to the methods.

Value
When applied to a flowFrame object, the result is an AnnotatedDataFrame describing the parameters recorded by the cytometer. For other objects it will usually return a vector of names used by the object for its calculations.
Methods

object = "filter"  Returns for all objects that inherit from filter a vector of parameters on which a gate is defined.

object = "parameterFilter"  see above

object = "setOperationFilter"  see above

object = "filterReference"  see above

object = "flowFrame"  Returns an AnnotatedDataFrame containing detailed descriptions about the measurement parameters of the flowFrame. For flowFrame objects there also exists a replacement method.

Author(s)

B. Ellis, N. Le Meur, F. Hahne

Examples

samp <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
parameters(samp)
print(samp@parameters@data)

parameterTransform-class

Class "parameterTransform"

Description

Link a transformation to particular flow parameters

Objects from the Class

Objects are created by using the %on% operator and are usually not directly instantiated by the user.

Slots

.Data: Object of class "function", the transformation function.

parameters: Object of class "character" The parameters the transformation is applied to.

transformationId: Object of class "character". The identifier for the object.

Extends

Class "transform", directly. Class "function", by class "transform", distance 2.

Methods

%on% signature(e1 = "filter", e2 = "parameterTransform"): Apply the transformation.

%on% signature(e1 = "parameterTransform", e2 = "flowFrame"): see above

parameters signature(object = "parameterTransform"): Accessor to the parameters slot.
polygonGate-class

Class "polygonGate"

Description

Class and constructor for 2-dimensional polygonal filter objects.

Usage

polygonGate(..., .gate, boundaries, filterId="defaultPolygonGate")

Arguments

filterId An optional parameter that sets the filterId of this gate.
.gate, boundaries A definition of the gate. This can be either a list or a named matrix as described below. Note the argument boundaries is deprecated and will go away in the next release.
... You can also directly describe a gate without wrapping it in a list or matrix, as described below.

Details

Polygons are specified by the coordinates of their vertices in two dimensions. The constructor is designed to be useful in both direct and programmatic usage. It takes either a list or a named matrix with 2 columns and at least 3 rows containing these coordinates. Alternatively, vertices can be given as named arguments, in which case the function tries to convert the values into a matrix.

Value

Returns a polygonGate object for use in filtering flowFrames or other flow cytometry objects.

Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

boundaries: Object of class "matrix". The vertices of the polygon in two dimensions. There need to be at least 3 vertices specified for a valid polygon.
parameters: Object of class "character", describing the parameter used to filter the flowFrame.
filterId: Object of class "character", referencing the filter.
Objects from the Class

Objects can be created by calls of the form `new("polygonGate", ...)` or by using the constructor `polygonGate`. Using the constructor is the recommended way of object instantiation:

Methods

`%in%` signature(x = "flowFrame", table = "polygonGate"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.

`show` signature(object = "polygonGate"): Print information about the filter.

Note

See the documentation in the `flowViz` package for plotting of `polygonGates`.

Author(s)

F.Hahne, B. Ellis N. Le Meur

See Also

`flowFrame, rectangleGate, ellipsoidGate, polytopeGate, filter` for evaluation of `rectangleGates` and `split` and `Subset` for splitting and subsetting of flow cytometry data sets based on that.

Examples

```r
## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Defining the gate
sqrcut <- matrix(c(300,300,600,600,50,300,300,50),ncol=2,nrow=4)
colnames(sqrcut) <- c("FSC-H","SSC-H")
pg <- polygonGate(filterId="nonDebris", boundaries= sqrcut)
pg

## Filtering using polygonGates
fres <- filter(dat, pg)
fres
summary(fres)

## The result of polygon filtering is a logical subset
Subset(dat, fres)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
split(dat, fres)
```
polytopeGate-class  Define filter boundaries

Description

Convenience methods to facilitate the construction of filter objects

Usage

polytopeGate(..., .gate, b, filterId="defaultPolytopeGate")

Arguments

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filterId</td>
<td>An optional parameter that sets the filterId of this gate.</td>
</tr>
<tr>
<td>.gate</td>
<td>A definition of the gate. This can be either a list, vector or matrix, described below.</td>
</tr>
<tr>
<td>b</td>
<td>Need documentation</td>
</tr>
<tr>
<td>...</td>
<td>You can also directly describe a gate without wrapping it in a list or matrix, as described below.</td>
</tr>
</tbody>
</table>

Details

These functions are designed to be useful in both direct and programmatic usage.

For rectangle gate in n dimensions, if n=1 the gate correspond to a range gate. If n=2, the gate is a rectangle gate. To use this function programatically, you may either construct a list or you may construct a matrix with n columns and 2 rows. The first row corresponds to the minimal value for each parameter while the second row corresponds to the maximal value for each parameter. The names of the parameters are taken from the column names as in the third example.

Rectangle gate objects can also be multiplied together using the * operator, provided that both gate have orthogonal axes.

For polygone gate, the boundaries are specified as vertices in 2 dimensions, for polytope gate objects as vertices in n dimensions.

For quadrant gates, the boundaries are specified as a named list or vector of length two.

Value

Returns a rectangleGate or polygonGate object for use in filtering flowFrames or other flow cytometry objects.

flowFrame, filter
Class "quadGate"

Description

Class and constructors for quadrant-type filter objects.

Usage

quadGate(..., .gate, filterId="defaultQuadGate")

Arguments

filterId  An optional parameter that sets the filterId of this filter. The object can
          later be identified by this name.
.gate     A definition of the gate for programmatic access. This can be either a named list
          or a named numeric vector, as described below.
...       The parameters of quadGates can also be directly described using named
          function arguments, as described below.

Details

quadGates are defined by two parameters, which specify a separation of a two-dimensional parameter space into four quadrants. The quadGate function is designed to be useful in both direct and programmatic usage:

For the interactive use, these parameters can be given as additional named function arguments, where the names correspond to valid parameter names in a flowFrame or flowSet. For a more programmatic approach, a named list or numeric vector of the gate boundaries can be passed on to the function as argument .gate.

Evaluating a quadGate results in four sub-populations, and hence in an object of class multipleFilterResult. Accordingly, quadGates can be used to split flow cytometry data sets.

Value

Returns a quadGate object for use in filtering flowFrames or other flow cytometry objects.

Extends

Class "parameterFilter", directly.
Class "concreteFilter", by class parameterFilter, distance 2.
Class "filter", by class parameterFilter, distance 3.

Slots

boundary: Object of class "numeric", length 2. The boundaries of the quadrant regions.
parameters: Object of class "character", describing the parameter used to filter the flowFrame.
filterId: Object of class "character", referencing the gate.
Objects from the Class

Objects can be created by calls of the form `new("quadGate", ...) or using the constructor `quadGate`. The latter is the recommended way of object instantiation:

Methods

`%in%` signature(x = "flowFrame", table = "quadGate"): The workhorse used to evaluate the gate on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.

`show` signature(object = "quadGate"): Print information about the gate.

Note

See the documentation in the `flowViz` package for plotting of `quadGates`.

F.Hahne, B. Ellis N. Le Meur

See Also

`flowFrame, flowSet, filter` for evaluation of `quadGates` and `split` for splitting of flow cytometry data sets based on that.

Examples

```r
## Loading example data
data <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Create directly. Most likely from a command line
quadGate(filterId="myQuadGate1", "FSC-H"=100, "SSC-H"=400)

## To facilitate programmatic construction we also have the following
quadGate(filterId="myQuadGate2", list("FSC-H"=100, "SSC-H"=400))

## Filtering using quadGates
qg <- quadGate(filterId="quad", "FSC-H"=600, "SSC-H"=400)
fres <- filter(data, qg)
fres
summary(fres)
names(fres)

## The result of quadGate filtering are multiple sub-populations
## and we can split our data set accordingly
split(data, fres)

## We can limit the splitting to one or several sub-populations
split(data, fres, population="FSC-H-SSC-H-")
split(data, fres, population=list(keep=c("FSC-H-SSC-H-", "FSC-H-SSC-H+")))
```
**quadratic-class**

*Class "quadratic"*

**Description**

Quadratic transform class defines a transformation defined by the function

\[
f(\text{parameter}, a) = a \ast \text{parameter}^2
\]

**Objects from the Class**

Objects can be created by calls to the constructor `quadratic(parameters,a,transformationId)`

**Slots**

- `.Data`: Object of class "function" ~~
- `a`: Object of class "numeric"-non zero mutiplicative constant
- `parameters`: Object of class "transformation"-flow parameter to be transformed
- `transformationId`: Object of class "character"-unique ID to reference the transformation

**Extends**

**Methods**

No methods defined with class "quadratic" in the signature.

**Note**

The quadratic transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a column vector. (See example below)

**Author(s)**

Gopalakrishnan N, F.Hahne

**References**

Gating-ML Candidate Recommendation for Gating Description in Flow Cytometry V 1.5

**See Also**

dg1polynomial,ratio,squareroot
quadraticTransform

Create the definition of a quadratic transformation function to be applied on a data set

**Examples**

```r
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
quad1 <- quadratic(parameters="FSC-H",a=2,transformationId="quad1")
transOut <- eval(quad1)(exprs(dat))
```

Create the definition of the quadratic Transformation that will be applied on some parameter via the transform method. The definition of this function is currently $x \leftarrow a \cdot x^2 + b \cdot x + c$

**Usage**

```r
quadraticTransform(transformationId="defaultQuadraticTransform", a = 1, b = 1, c = 0)
```

**Arguments**

- `transformationId`: character string to identify the transformation
- `a`: double that corresponds to the quadratic coefficient in the equation
- `b`: double that corresponds to the linear coefficient in the equation
- `c`: double that corresponds to the intercept in the equation

**Value**

Returns an object of class `transform`.

**Author(s)**

N. Le Meur

**See Also**

`transform-class`, `transform`

**Examples**

```r
samp <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))
quadTrans <- quadraticTransform(transformationId="Quadratic-transformation", a=1, b=1, c=0)
dataTransform <- transform(samp,`FSC-H`=quadTrans(`FSC-H`))
```
randomFilterResult-class

    Class "randomFilterResult"

Description

Container to store the result of applying a filter on a flowFrame object

Slots

  subset: Object of class "numeric"
  frameId: Object of class "character" referencing the flowFrame object filtered. Used for
           sanity checking.
  filterDetails: Object of class "list" describing the filter applied
  filterId: Object of class "character" referencing the filter applied

Extends

Class "filterResult", directly. Class "filter", by class "filterResult", distance 2.

Author(s)

ratio-class

    Class "ratio"

Description

ratio transform calculates the ratio of two parameters defined by the function

\[ f(\text{parameter}_1, \text{parameter}_2) = \frac{\text{parameter}_1}{\text{parameter}_2} \]

Objects from the Class

Objects can be created by calls to the constructor \texttt{ratio(\text{parameter}_1, \text{parameter}_2, \text{transformationId})}.

Slots

  .Data: Object of class "function" ~~
  numerator: Object of class "transformation" -flow parameter to be transformed
  denominator: Object of class "transformation" -flow parameter to be transformed
  transformationId: Object of class "character" unique ID to reference the transformation
Extends

Class "transform", directly. Class "transformation", by class "transform", distance 2.
Class "characterOrTransformation", by class "transform", distance 3.

Methods

No methods defined with class "ratio" in the signature.

Note

The ratio transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with one column. (See example below)

transOut <- eval(rat1)(exprs(dat))

read.FCSheader

Read the TEXT section of a FCS file

Description

Read (part of) the TEXT section of a Data File Standard for Flow Cytometry that contains FACS keywords.

Usage

read.FCSheader(files, path=".", keyword=NULL)

Arguments

files Character vector of filenames.
path Directory where to look for the files.
keyword An optional character vector that specifies the FCS keyword to read.
Details

The function `read.FCSheader` works with the output of the FACS machine software from a number of vendors (FCS 2.0, FCS 3.0 and List Mode Data LMD). The output of the function is the TEXT section of the FCS files. The user can specify some keywords to limit the output to the information of interest.

Value

A list of character vector. Each element of the list correspond to one FCS file.

Examples

```r
samp <- read.FCSheader(system.file("extdata", "0877408774.B08", package="flowCore"))
samp

samp <- read.FCSheader(system.file("extdata", "0877408774.B08", package="flowCore"), keyword=c("$DATE", "$FIL"))
samp
```

---

**read.FCS**  
*Read an FCS file*

Description

Check validity and Read Data File Standard for Flow Cytometry

Usage

```r
isFCSfile(files)

read.FCS(filename, transformation="linearize", which.lines=NULL, debug=FALSE, alter.names=FALSE, column.pattern=NULL, decades=0, ncdf = FALSE, min.limit=NULL)

cleanup()
```
read.FCS

Arguments

files A vector of filenames
filename Character of length 1: filename
transformation An character string that defines the type of transformation. Valid values are linearize (default) or scale. The linearize transformation applies the appropriate power transform to the data while the scale transformation scales all columns to [0, 10^decades], defaulting to decades=0 as in the FCS4 specification. A logical can also be used: TRUE is equal to linearize and FALSE corresponds to no transformation.
which.lines Numeric vector to specify the indices of the lines to be read. If NULL all the records are read, if of length 1, a random sample of the size indicated by which.lines is read in.
debug boolean indicating whether or not to print the debugging statements, default is TRUE
alter.names boolean indicating whether or not we should rename the columns to valid R names using make.names. The default is FALSE.
column.pattern An optional regular expression defining parameters we should keep when loading the file. The default is NULL.
decades When scaling is activated, the number of decades to use for the output.
ncdf Instead of reading all data into memory, this switches to file-based data storage. A netCDF file is creates for each flowFrame in the .flowCoreNcdf subdirectory. For large data sets this significantly reduces the memory profile of the R session, to the cost of speed and disk space. The exprs and exprs<- methods make sure that the user always gets a matrix of data values. Please note that currently all operations that call exprs<- either explicitely or implicitely, will result in the creation of a new netCDF file. This behaviour may change in the future. Currently the software does not remove any of the netCDF files and it is up to the user to do clean up. The easiest way to do that is to delete the whole netCDF directory. To this end, one can envoke the cleanup function.
min.limit The minimum value in the data range that is allowed. Some instruments produce extreme artifactual values. The positive data range for each parameter is completely defined by the measurement range of the instrument and all larger values are set to this threshold. The lower data boundary is not that well defined, since compensation might shift some values below the original measurement range of the instrument. The default value of -111 copies the behavior of flowJo. It can be set to an arbitrary number or to NULL, in which case the original values are kept.

Details

The function isFCSfile determines whether its arguments are valid FCS files.
The function read.FCS works with the output of the FACS machine software from a number of vendors (FCS 2.0, FCS 3.0 and List Mode Data LMD). However, the FCS 3.0 standard includes some options that are not yet implemented in this function. If you need extensions, please let me know. The output of the function is an object of class flowFrame.
For specifications of FCS 3.0 see http://www.isac-net.org and the file ../doc/fcs3.html in the doc directory of the package.
The `nlines` and `sampling` arguments allow you to read a subset of the record as you might not want to read the thousands of events recorded in the FCS file. The `which.lines` argument allows you to read a specific number of records.

**Value**

- `isFCSfile` returns a logical vector.
- `read.FCS` returns an object of class `flowFrame` that contains the data in the `exprs` slot, the parameters monitored in the `parameters` slot and the keywords and value saved in the header of the FCS file.

nrow(subset)
```

---

**read.flowSet**  
**Read a set of FCS files**

**Description**

Read one or several FCS files: Data File Standard for Flow Cytometry

**Usage**

```r
read.flowSet(files= NULL, path=".", pattern= NULL, phenoData, 
descriptions, name.keyword, alter.names= FALSE, transformation = 
"linearize", which.lines= NULL, debug = FALSE, column.pattern = NULL, 
decades= 0, sep=" \t", as.is= TRUE, name, ncdf= FALSE, ...)```
Arguments

files: Optional character vector with filenames.

path: Directory where to look for the files.

pattern: This argument is passed on to `dir`, see details.

phenoData: An object of class `AnnotatedDataFrame`, character or a list of values to be extracted from the `flowFrame` object, see details.

descriptions: Character vector to annotate the object of class `flowSet-class{flowSet}`.

name.keyword: An optional character vector that specifies which FCS keyword to use as the sample names. If this is not set, the GUID of the FCS file is used for sample Names, and if that is not present (or not unique), then the file names are used.

alter.names: see `read.FCS` for details.

transformation: see `read.FCS` for details.

which.lines: see `read.FCS` for details.

decades: see `read.FCS` for details.

debug: see `read.FCS` for details.

column.pattern: see `read.FCS` for details.

sep: Separator character that gets passed on to `read.AnnotatedDataFrame`.

as.is: Logical that gets passed on to `read.AnnotatedDataFrame`. This controls the automatic coercion of characters to factors in the phenoData slot.

name: An optional character scalar used as name of the object.

code: In place of reading all data into memory, this switches to file-based data storage. See `read.FCS` for details.

...: Further arguments that get passed on to `read.AnnotatedDataFrame`, see details.

Details

There are four different ways to specify the file from which data is to be imported:

First, if the argument `phenoData` is present and is of class `AnnotatedDataFrame`, then the file names are obtained from its sample names (i.e. column `name`). The column is mandatory, and an error will be generated if it is not there. Alternatively, the argument `phenoData` can be of class character, in which case this function tries to read a `AnnotatedDataFrame` object from the file with that name by calling `read.AnnotatedDataFrame(file.path(path,phenoData),...)`.

In some cases the file names are not a reasonable selection criterion and the user might want to import files based on some keywords within the file. One or several keyword value pairs can be given as the phenoData argument in form of a named list.

Third, if the argument `phenoData` is not present and the argument `files` is not NULL, then `files` is expected to be a character vector with the file names.

Fourth, if neither the argument `phenoData` is present nor `files` is not NULL, then the file names are obtained by calling `dir(path, pattern)`.

Value

An object of class `flowSet-class{flowSet}`.
rectangleGate-class

Author(s)

F. Hahne, N. Le Meur, B. Ellis

Examples

```r
fcs.loc <- system.file("extdata", package="flowCore")
file.location <- paste(fcs.loc, dir(fcs.loc), sep="/"")
samp <- read.flowSet(file.location[1:3])
```

rectangleGate-class

Class "rectangleGate"

Description

Class and constructor for n-dimensional rectangular filter objects.

Usage

```r
rectangleGate(..., .gate, filterId="defaultRectangleGate")
```

Arguments

- `filterId` An optional parameter that sets the filterId of this gate. The object can later be identified by this name.
- `...` You can also directly provide the boundaries of a rectangleGate as additional named arguments, as described below.
- `.gate` A definition of the gate. This can be either a list, or a matrix, as described below.

Details

This class describes a rectangular region in n dimensions, which is a Cartesian product of n orthogonal intervals in these dimensions. n=1 corresponds to a range gate, n=2 to a rectangle gate, n=3 corresponds to a box region and n>3 to a hyper-rectangular regions. Intervals may be open on one side, in which case the value for the boundary is supposed to be Inf or -Inf, respectively. rectangleGates are inclusive, that means that events on the boundaries are considered to be in the gate.

The constructor is designed to be useful in both direct and programmatic usage. To use it programatically, you may either construct a named list or you may construct a matrix with n columns and 2 rows. The first row corresponds to the minimal value for each parameter while the second row corresponds to the maximal value for each parameter. The names of the parameters are taken from the column names or from the list names, respectively. Alternatively, the boundaries of the rectangleGate can be given as additional named arguments, where each of these arguments should be a numeric vector of length 2; the function tries to collapse these boundary values into a matrix.
Note that boundaries of `rectangleGates` where \( \min > \max \) are syntactically valid, however when evaluated they will always be empty.

`rectangleGate` objects can also be multiplied using the \( \ast \) operator, provided that both gates have orthogonal axes. This results in higher-dimensional `rectangleGates`. The inverse operation of subsetting by parameter name(s) is also available.

Evaluating a `rectangleGate` generates an object of class `logicalFilterResult`. Accordingly, `rectangleGates` can be used to subset and to split flow cytometry data sets.

**Value**

Returns a `rectangleGate` object for use in filtering `flowFrame`s or other flow cytometry objects.

**Extends**

Class "`parameterFilter`", directly.
Class "`concreteFilter`", by class `parameterFilter`, distance 2.
Class "`filter`", by class `parameterFilter`, distance 3.

**Slots**

- `min,max`: Objects of class "`numeric`". The minimum and maximum values of the n-dimensional rectangular region.
- `parameters`: Object of class "`character`", indicating the parameters for which the `rectangleGate` is defined.
- `filterId`: Object of class "`character`", referencing the filter.

**Objects from the Class**

Objects can be created by calls of the form `new("rectangleGate", ...)`, by using the constructor `rectangleGate` or by combining existing `rectangleGates` using the \( \ast \) method.

Using the constructor is the recommended way of object instantiation:

**Methods**

- `%in%` signature(x = "flowFrame", table = "rectangleGate"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.
- `show` signature(object = "rectangleGate"): Print information about the filter.
- \( \ast \) signature(e1 = "rectangleGate", e2 = "rectangleGate"): combining two `rectangleGates` into one higher dimensional representation.
- signature(x = "rectangleGate", i = "character"): Subsetting of a `rectangleGate` by parameter name(s). This is essentially the inverse to \( \ast \).

**Note**

See the documentation in the `flowViz` package for details on plotting of `rectangleGates`.

## Loading example data
dat <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

#Create directly. Most likely from a command line
rectangleGate(filterId="myRectGate", "FSC-H"=c(200, 600), "SSC-H"=c(0, 400))

#To facilitate programmatic construction we also have the following
rg <- rectangleGate(filterId="myRectGate", list("FSC-H"=c(200, 600), "SSC-H"=c(0, 400))
mat <- matrix(c(200, 600, 0, 400), ncol=2, dimnames=list(c("min", "max"), c("FSC-H", "SSC-H")));
rg <- rectangleGate(filterId="myRectGate", gate=mat)

## Filtering using rectangleGates
fres <- filter(dat, rg)
fres
summary(fres)

## The result of rectangle filtering is a logical subset
Subset(dat, fres)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
split(dat, fres)

## Multiply rectangle gates
rg1 <- rectangleGate(filterId="FSC-", "FSC-H"=c(-Inf, 50))
rg2 <- rectangleGate(filterId="SSC+", "SSC-H"=c(50, Inf))
rg1 * rg2

## Subset rectangle gates
rg["FSC-H"]
```

sampleFilter-class Class "sampleFilter"

Description

This non-parameter filter selects a number of events from the primary flowFrame.

Usage

```r
sampleFilter(size, filterId="defaultSampleFilter")
```
Arguments

- **filterId**: An optional parameter that sets the `filterId` of this `filter`. The object can later be identified by this name.
- **size**: The number of events to select.

Details

Selects a number of events without replacement from a `flowFrame`.

Value

Returns a `sampleFilter` object for use in filtering `flowFrames` or other flow cytometry objects.

Extends

Class "concreteFilter", directly.
Class "filter", by class `concreteFilter`, distance 2.

Slots

- **size**: Object of class "numeric". Then number of events that are to be selected.
- **filterId**: A character vector that identifies this `filter`.

Objects from the Class

Objects can be created by calls of the form `new("sampleFilter", ...)` or using the constructor `sampleFilter`. The latter is the recommended way of object instantiation:

Methods

- **%in%** `signature(x = "flowFrame", table = "sampleFilter")`: The workhorse used to evaluate the gate on data. This is usually not called directly by the user, but internally by calls to the `filter` methods.
- **show** `signature(object = "sampleFilter")`: Print information about the gate.

sf

## Filtering using sampleFilters
fres <- filter(dat, sf)
fres
summary(fres)

## The result of sample filtering is a logical subset
Subset(dat, fres)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
split(dat, fres)

---

**scaleTransform**

Create the definition of a scale transformation function to be applied on a data set

Description

Create the definition of the scale Transformation that will be applied on some parameter via the transform method. The definition of this function is currently \( x = \frac{(x-a)}{(b-a)} \). The transformation would normally be used to convert to a 0-1 scale. In this case, b would be the maximum possible value and a would be the minimum possible value.

Usage

scaleTransform(transformationId="defaultScaleTransform", a, b)

Arguments

- **transformationId**
  - character string to identify the transformation
- **a**
  - double that corresponds to the value that will be transformed to 0
- **b**
  - double that corresponds to the value that will be transformed to 1

Value

Returns an object of class transform.

### spillover

**Compute a spillover matrix from a flowSet**

#### Description
Spillover information for a particular experiment is often obtained by running several tubes of beads or cells stained with a single color that can then be used to determine a spillover matrix for use with `compensate`.

#### Usage
```r
## S4 method for signature 'flowSet'
spillover(x, unstained = NULL, patt = NULL, fsc = "FSC-A", ssc = "SSC-A", method = "median")
```

#### Arguments
- `x` A `flowSet` of compensation beads or cells
- `unstained` The name of index of the unstained negative control
- `patt` An optional regular expression defining which parameters should be considered.
- `fsc` The name or index of the forward scatter parameter
- `ssc` The name or index of the side scatter parameter
- `method` The statistic to use for calculation. Traditionally, this has been the median so it is the default. The mean is sometimes more stable.
Details

The algorithm used is fairly simple. First, using the scatter parameters, we restrict ourselves to the most closely clustered population to reduce the amount of debris. The selected statistic is then calculated on all appropriate parameters and the unstained values swept out of the matrix. Every sample is then normalized to [0,1] with respect to the maximum value of the sample, giving the spillover in terms of a proportion of the primary channel intensity.

Value

A matrix for each of the parameters

compensate

split-methods

Methods to split flowFrames and flowSets according to filters

Description

Divide a flow cytometry data set into several subset according to the results of a filtering operation. There are also methods available to split according to a factor variable.

Details

The splitting operation in the context of flowFrames and flowSets is the logical extension of subsetting. While the latter only returns the events contained within a gate, the former splits the data into the groups of events cotained within and those not contained within a particular gate. This concept is extremely useful in applications where gates describe the distinction between positivity and negativity for a particular marker.

The flow data structures in flowCore can be split into subsets on various levels:

- **flowFrame**: row-wise splitting of the raw data. In most cases, this will be done according to the outcome of a filtering operation, either using a filter that identifirs more than one sub-pouulation or by a logical filter, in which case the data is split into two populations: "in the filter" and "not in the filter". In addition, the data can be split according to a factor (or a numeric or character vector that can be coerced into a factor).

- **flowSet**: can be either split into subsets of flowFrames according to a factor or a vector that can be coerced into a factor, or each individual flowFrame into subpopulations based on the filters or filterResults provided as a list of equal length.

Splitting has a special meaning for filters that result in multipleFilterResults or manyFilterResults, in which case simple subsetting doesn’t make much sense (there are multiple populations that
are defined by the gate and it is not clear which of those should be used for the subsetting operation. Accordingly, splitting of multipleFilterResults creates multiple subsets. The argument population can be used to limit the output to only one or some of the resulting subsets. It takes as values a character vector of names of the populations of interest. See the documentation of the different filter classes on how population names can be defined and the respective default values. For splitting of logicalFilterResults, the population argument can be used to set the population names since there is no reasonable default other than the name of the gate. The content of the argument prefix will be prepended to the population names and '+' or '-' are finally appended allowing for more flexible naming schemes.

The default return value for any of the split methods is a list, but the optional logical argument filterSet can be used to return a flowSet instead. This only applies when splitting flowFrames, splitting of flowSets always results in lists of flowSet objects.

Methods

**flowFrame** methods:

x = "flowFrame", f = "ANY", drop = "ANY" Catch all input and cast an error if there is no method for \( f \) to dispatch to.

x = "flowFrame", f = "factor", drop = "ANY" Split a flowFrame by a factor variable. Length of \( f \) should be the same as \( \text{nrow}(x) \), otherwise it will be recycled, possibly leading to undesired outcomes. The optional argument drop works in the usual way, in that it removes empty levels from the factor before splitting.

x = "flowFrame", f = "character", drop = "ANY" Coerce \( f \) to a factor and split on that.

x = "flowFrame", f = "numeric", drop = "ANY" Coerce \( f \) to a factor and split on that.

x = "flowFrame", f = "filter", drop = "ANY" First applies the filter to the flowFrame and then splits on the resulting filterResult object.

x = "flowFrame", f = "filterSet", drop = "ANY" First applies the filterSet to the flowFrame and then splits on the resulting final filterResult object.

x = "flowFrame", f = "logicalFilterResult", drop = "ANY" Split into the two subpopulations (in and out of the gate). The optional argument population can be used to control the names of the results.

x = "flowFrame", f = "manyFilterResult", drop = "ANY" Split into the several subpopulations identified by the filtering operation. Instead of returning a list, the additional logical argument codeflowSet makes the method return an object of class flowSet. The optional population argument takes a character vector indicating the subpopulations to use for splitting (as identified by the population name in the filterDetails slot).

x = "flowFrame", f = "multipleFilterResult", drop = "ANY" Split into the several subpopulations identified by the filtering operation. Instead of returning a list, the additional logical argument codeflowSet makes the method return an object of class flowSet. The optional population argument takes a character vector indicating the subpopulations to use for splitting (as identified by the population name in the filterDetails slot). Alternatively, this can be a list of characters, in which case the populations for each list item are collapsed into one flowFrame.

**flowSet** methods:

x = "flowSet", f = "ANY", drop = "ANY" Catch all input and cast an error if there is no method for \( f \) to dispatch to.
Split a `flowSet` by a factor variable. Length of `f` needs to be the same as `length(x)`. The optional argument `drop` works in the usual way, in that it removes empty levels from the factor before splitting.

Coerce `f` to a factor and split on that.

Coerce `f` to a factor and split on that.

Split a `flowSet` by a list of `filterResult`s (as typically returned by filtering operations on a `flowSet`). The length of the list has to be equal to the length of the `flowSet` and every list item needs to be a `filterResult` of equal class with the same parameters. Instead of returning a list, the additional logical argument `codeflowSet` makes the method return an object of class `flowSet`. The optional `population` argument takes a character vector indicating the subpopulations to use for splitting (as identified by the population name in the `filterDetails` slot). Alternatively, this can be a list of characters, in which case the populations for each list item are collapsed into one `flowFrame`. Note that using the `population` argument implies common population names for all `filterResult`s in the list and there will be an error if this is not the case.

F Hahne, B. Ellis, N. Le Meur

Examples

data(GvHD)
qGate <- quadGate(filterId="qg", "FSC-H"=200, "SSC-H"=400)

## split a flowFrame by a filter that creates
## a multipleFilterResult
samp <- GvHD[[1]]
fres <- filter(samp, qGate)
split(samp, qGate)

## return a flowSet rather than a list
split(samp, fres, flowSet=TRUE)

## only keep one population
names(fres)

## split the whole set, only keep two populations
## split(GvHD, qGate, population=c("FSC-Height+SSC-Height+",
## "FSC-Height-SSC-Height+"))

## now split the flowSet according to a factor
split(GvHD, pData(GvHD)$Patient)
Description

The split scale transformation class defines a transformation that has a logarithmic scale at high values and a linear scale at low values. The transition points are chosen so that the slope of the transformation is continuous at the transition points.

The split scale transformation is defined by the function

\[
f(\text{parameter}, r, \text{maxValue}, \text{transitionChannel}) = a \times \text{parameter} + b \quad \text{parameter} \leq t
\]

\[
\log_{10}(c \times \text{parameter}) \times \frac{r}{d} \quad \text{parameter} > t
\]

where,

\[
b = \frac{\text{transitionChannel}}{2}
\]

\[
d = \frac{2 \times \log_{10}(c) \times r}{\text{transitionChannel}} + \log_{10}(\text{maxValue})
\]

\[
t = 10^{\log_{10}\text{t}}
\]

\[
a = \frac{\text{transitionChannel}}{2 \times \text{t}}
\]

\[
\log_{10}\text{ct} = \frac{(a \times \text{t} + b) \times d}{r}
\]

\[
c = 10^{\log_{10}\text{ct}}
\]

Objects from the Class

Objects can be created by calls to the constructor `splitscale(parameters, r, maxValue, transitionChannel, transformationId)`.

Slots

- **.Data**: Object of class "function" ~
- **r**: Object of class "numeric" - a positive value indicating the range of the logarithmical part of the display
- **maxValue**: Object of class "numeric" - a positive value indicating the maximum value the transformation is applied to
- **transitionChannel**: Object of class "numeric" - non-negative value that indicates where to split the linear vs. logarithmical transformation
- **parameters**: Object of class "transformation" - flow parameter to be transformed
- **transformationId**: Object of class "character" - unique ID to reference the transformation

Extends

Methods

No methods defined with class "splitscale" in the signature.
Note

The transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a matrix with a single column. (See example below)

Examples

dat <- read.FCS(system.file("extdata","0877408774.B08",package="flowCore")
spl1<-splitscale("FSC-H",r=768,maxValue=10000,transitionChannel=256)
transOut<-eval(spl1)(exprs(dat))

splitScaleTransform

Compute the split-scale transformation describe by FL. Battye

Description

The split scale transformation described by Francis L. Battye [B15] (Figure 13) consists of a logarithmic scale at high values and a linear scale at low values with a fixed transition point chosen so that the slope (first derivative) of the transform is continuous at that point. The scale extends to the negative of the transition value that is reached at the bottom of the display.

Usage

splitScaleTransform(transformationId="defaultSplitscaleTransform", maxValue=1023)

Arguments

transformationId

A name to assign to the transformation. Used by the transform/filter integration routines.

maxValue

Maximum value the transformation is applied to, e.g., 1023

transitionChannel

Where to split the linear versus the logarithmical transformation, e.g., 64

r

Range of the logarithm part of the display, i.e. it may be expressed as the maxChannel - transitionChannel considering the maxChannel as the maximum value to be obtained after the transformation.
Value

Returns values giving the inverse of the biexponential within a certain tolerance. This function should be used with care as numerical inversion routines often have problems with the inversion process due to the large range of values that are essentially 0. Do not be surprised if you end up with population splitting about $w$ and other odd artifacts.

squareroot-class  Class "squareroot"

Description

Square root transform class defines a transformation defined by the function

$$f(\text{parameter}, a) = \sqrt{|\frac{\text{parameter}}{a}|}$$

Objects from the Class

Objects can be created by calls to the constructor `squareroot(parameters, a, transformationId)`

Slots

- `.Data`: Object of class "function" ~-
- `a`: Object of class "numeric" - non zero multiplicative constant
- `parameters`: Object of class "transformation" - flow parameter to be transformed
- `transformationId`: Object of class "character" - unique ID to reference the transformation
**Subset**

**Extends**

**Methods**

No methods defined with class "squareroot" in the signature.

**Note**

The squareroot transformation object can be evaluated using the eval method by passing the data frame as an argument. The transformed parameters are returned as a column vector. (See example below)

**Examples**

```r
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
sqrt1<-squareroot (parameters="FSC-H",a=2,transformationId="sqrt1")
transOut<-eval(sqrt1)(exprs(dat))
```

---

**Description**

An equivalent of a `subset` function for `flowFrame` or a `flowSet` object. Alternatively, the regular subsetting operators can be used for most of the topics documented here.

**Usage**

`Subset(x, subset, ...)`

**Arguments**

- `x` The flow object, frame or set, to subset.
- `subset` A filter object or, in the case of `flowSet` subsetting, a named list of filters.
- `...` Like the original `subset` function, you can also select columns.
Details

The Subset method is the recommended method for obtaining a flowFrame that only contains events consistent with a particular filter. It is functionally equivalent to `frame[as(filter(frame, subset), "logical"),]` when used in the flowFrame context. Used in the flowSet context, it is equivalent to using `fsApply` to apply the filtering operation to each flowFrame.

Additionally, using Subset on a flowSet can also take a named list as the subset. In this case, the names of the list object should correspond to the sampleNames of the flowSet, allowing a different filter to be applied to each frame. If not all of the names are used or excess names are present, a warning will be generated but the valid filters will be applied for the rare instances where this is the intended operation. Note that a filter operation will generate a list of filterResult objects that can be used directly with Subset in this manner.

Value

Depending on the original context, either a flowFrame or a flowSet.

Author(s)

B. Ellis

See Also

split, subset

Examples

```r
sample <- read.flowSet(path=system.file("extdata", package="flowCore"),
  pattern="0877408774")
result <- filter(sample, rectangleGate("FSC-H"=c(-Inf, 1024)))
result
Subset(sample, result)
```

---

subsettingActionItem-class

Class "subsettingActionItem"

Description

Class and method to capture subsetting operations in a flow cytometry workflow.

Usage

```r
subsettingActionItem(ID = paste("subActionRef", guid(), sep = "_"),
  name = paste("action", identifier(get(subsetting)), sep = "_"),
  parentView, subsetting, workflow)
```
subsettingActionItem-class

Arguments

- workflow: An object of class `workFlow` for which a view is to be created.
- ID: A unique identifier of the view, most likely created by using the internal `guid` function.
- name: A more human-readable name of the view.
- parentView, subsetting: References to the parent `view` and `subsetting` objects, respectively.

Details

`subsettingActionItems` provide a means to bind subsetting operations in a workflow. Each `subsettingActionItem` represents a single subsetting.

Value

A reference to the `subsettingActionItem` that is created inside the `workFlow` environment as a side effect of calling the `add` method.

A `subsettingActionItem` object for the constructor.

Objects from the Class

Objects should be created using the `add` method, which creates a `subsettingActionItem` from a `normalization` object and directly assigns it to a `workFlow`. Alternatively, one can use the `subsettingActionItem` constructor function for more programmatic access.

Slots

- **subsetting**: Object of class "fcSubsettingReference". A reference to the subsetting object that is used for the operation.
- **ID**: Object of class "character". A unique identifier for the actionItem.
- **name**: Object of class "character". A more human-readable name
- **parentView**: Object of class "fcViewReference". A reference to the parent view the subsettingActionItem is applied on.
- **env**: Object of class "environment". The evaluation environment in the `workFlow`.

Extends

Class "actionItem", directly.

Methods

- **print** signature(x = "subsettingActionItem"): Print details about the object.
- **Rm** signature(symbol = "subsettingActionItem", envir = "workFlow", subSymbol = "character"): Remove a subsettingActionItem from a workFlow. This method is recursive and will also remove all dependent views and actionItems.
- **show** signature(object = "subsettingActionItem"): Print details about the object.

Examples

showClass("view")

subsetting-class  Class "subsetting"

Description

Class and methods to subset a a flowSet. This is only needed for method dispatch in the workFlow framework.

Usage

subsetting(indices, subsettingId="defaultSubsetting")

Arguments

indices  Character or numeric vector of sample names.
subsettingId  The identifier for the subsetting object.

Details

The class mainly existst for method dispatch in the workflow tools.

Value

A subsetting object.

Objects from the Class

Objects should be created using the constructor subsetting(). See the Usage and Arguments sections for details.

Slots

subsettingId:  Object of class "character". An identifier for the object.
indices:  Object of class "numericOrCharacter". Indices into a flowSet.

Methods

add  signature(wf = "workFlow", action = "subsetting"): The constructor for the workFlow.
identifier<-  signature(object = "subsetting", value = "character"): Set method for the identifier slot.
identifier  signature(object = "subsetting"): Get method for the identifier slot.
show  signature(object = "subsetting"): Show details about the object.
subsettingView-class

Author(s)
F. Hahne

Description
Class and method to capture the result of subsetting operations in a flow cytometry workflow.

Usage

subsettingView(workflow, ID=paste("subViewRef", guid(), sep="_"),
   name="default", action, data)

Arguments

  workflow  An object of class workFlow for which a view is to be created.
  ID        A unique identifier of the view, most likely created by using the internal guid function.
  name      A more human-readable name of the view.
  data, action References to the data and actionItem objects, respectively.

Value

A reference to the subsettingView that is created inside the workFlow environment as a side effect of calling the add method.
A subsettingView object for the constructor.

Objects from the Class

Objects should be created using the add method, which creates a subsettingView from a subsetting object and directly assigns it to a workFlow. Alternatively, one can use the subsettingView constructor function for more programmatic access.

Slots

  ID: Object of class "character". A unique identifier for the view.
  name: Object of class "character". A more human-readable name
  action: Object of class "fcActionReference". A reference to the actionItem that generated the view.
  env: Object of class "environment". The evaluation environment in the workFlow.
  data: Object of class "fcDataReference" A reference to the data that is associated to the view.
summarizeFilter-methods

Extends

Class "view", directly.

Methods

Rm signature(symbol = "subsettingView", envir = "workFlow", subSymbol = "character"): Remove a subsettingView from a workFlow. This method is recursive and will also remove all dependent views and actionItems.

Author(s)

Florian Hahne

See Also

workFlow, view, gateView, transformView, compensateView, actionItem

Examples

showClass("view")

summarizeFilter-methods

Methods for function summarizeFilter

Description

Internal methods to populate the filterDetails slot of a filterResult object.

Methods

result = "filterResult", filter = "filter" summarizeFilter methods are called during the process of filtering. Their output is a list, and it can be arbitrary data that should be stored along with the results of a filtering operation.

result = "filterResult", filter = "filterReference" see above
result = "filterResult", filter = "parameterFilter" see above
result = "filterResult", filter = "subsetFilter" see above
result = "logicalFilterResult", filter = "norm2Filter" see above
result = "logicalFilterResult", filter = "parameterFilter" see above
result = "multipleFilterResult", filter = "curv1Filter" see above
result = "multipleFilterResult", filter = "curv2Filter" see above
result = "multipleFilterResult", filter = "parameterFilter" see above
**timeFilter-class**

Class "timeFilter"

**Description**

Define a **filter** that removes stretches of unusual data distribution within a single parameter over time. This can be used to correct for problems during data acquisition like air bubbles or clods.

**Usage**

```r
timeFilter(..., bandwidth=0.75, binSize, timeParameter, filterId="defaultTimeFilter")
```

**Arguments**

- **...**: The names of the parameters on which the filter is supposed to work on. Names can either be given as individual arguments, or as a list or a character vector.
- **filterId**: An optional parameter that sets the `filterId` slot of this gate. The object can later be identified by this name.
- **bandwidth, binSize**: Numerics used to set the `bandwidth` and `binSize` slots of the object.
- **timeParameter**: Character used to set the `timeParameter` slot of the object.

**Details**

Clods and disturbances in the laminar flow of a FACS instrument can cause temporal aberrations in the data acquisition that lead to artifactual values. **timeFilters** try to identify such stretches of disturbance by computing local variance and location estimates and to remove them from the data.

**Value**

Returns a **timeFilter** object for use in filtering **flowFrames** or other flow cytometry objects.

**Extends**

- Class "parameterFilter", directly.
- Class "concreteFilter", by class parameterFilter, distance 2.
- Class "filter", by class parameterFilter, distance 3.

**Slots**

- **bandwidth**: Object of class "numeric". The sensitivity of the filter, i.e., the amount of local variance of the signal we want to allow.
- **binSize**: Object of class "numeric". The size of the bins used for the local variance and location estimation. If NULL, a reasonable default is used when evaluating the filter.
- **timeParameter**: Object of class "character", used to define the time domain parameter. If NULL, the filter tries to guess the time domain from the flowFrame.
**parameters:** Object of class "character", describing the parameters used to filter the flowFrame.

**filterId:** Object of class "character", referencing the filter.

**Objects from the Class**

Objects can be created by calls of the form `new("timeFilter", ...)` or using the constructor `timeFilter`. Using the constructor is the recommended way of object instantiation:

**Methods**

%in% signature(x = "flowFrame", table = "timeFilter"): The workhorse used to evaluate the filter on data. This is usually not called directly by the user.

**show** signature(object = "timeFilter"): Print information about the filter.

**Note**

See the documentation of `timeLinePlot` in the `flowViz` package for details on visualizing temporal problems in flow cytometry data.

**Author(s)**

Florian Hahne

**See Also**

`flowFrame`, `filter` for evaluation of `timeFilters` and `split` and `Subset` for splitting and subsetting of flow cytometry data sets based on that.

**Examples**

```r
## Loading example data
data(GvHD)
dat <- GvHD[1:10]

## create the filter
tf <- timeFilter("SSC-H", bandwidth=1, filterId="myTimeFilter")
tf

## Visualize problems
## Not run:
library(flowViz)
timeLinePlot(dat, "SSC-H")
## End(Not run)

## Filtering using timeFilters
fres <- filter(dat, tf)
fres[[1]]
summary(fres[[1]])
summary(fres[[7]])

## The result of rectangle filtering is a logical subset
cleanDat <- Subset(dat, fres)

## Visualizing after cleaning up
```
## Not run:
```
timelinePlot(cleanDat, "SSC-H")
```
## End(Not run)

## We can also split, in which case we get those events in and those
## not in the gate as separate populations
```
allDat <- split(dat[[7]], fres[[7]])
par(mfcol=c(1,3))
plot(exprs(dat[[7]])[, "SSC-H"], pch=".")
plot(exprs(cleanDat[[7]])[, "SSC-H"], pch=".")
plot(exprs(allDat[[2]])[, "SSC-H"], pch=".")
```

**transformActionItem-class**

Class "transformActionItem"

### Description

Class and method to capture transformation operations in a flow cytometry workflow.

### Usage

```
transformActionItem(ID = paste("transActionRef", guid(), sep = "_"),
                   name=paste("action", identifier(get(transform)), sep = "_"),
                   parentView, transform, workflow)
```

### Arguments

- **workflow**
  - An object of class `workFlow` for which a view is to be created.
- **ID**
  - A unique identifier of the view, most likely created by using the internal `guid` function.
- **name**
  - A more human-readable name of the view.
- **parentView, transform**
  - References to the parent `view` and `transform` objects, respectively.

### Details

`transformActionItems` provide a means to bind transformation operations in a workflow. Each `transformActionItem` represents a single `transform`.

### Value

A reference to the `transformActionItem` that is created inside the `workFlow` environment as a side effect of calling the `add` method.

A `transformActionItem` object for the constructor.
Objects from the Class

Objects should be created using the add method, which creates a transformActionItem from a transform object and directly assigns it to a workFlow. Alternatively, one can use the transformActionItem constructor function for more programmatic access.

Slots

- `transform`: Object of class "fcTransformReference". A reference to the transform object that is used for the transformation operation.
- `ID`: Object of class "character". A unique identifier for the actionItem.
- `name`: Object of class "character". A more human-readable name
- `parentView`: Object of class "fcViewReference". A reference to the parent view the transformActionItem is applied on.
- `env`: Object of class "environment". The evaluation environment in the workFlow.

Extends

Class "actionItem", directly.

Methods

- `print` signature(x = "transformActionItem"): Print details about the object.
- `Rm` signature(symbol = "transformActionItem", envir = "workFlow", subSymbol = "character"): Remove a transformActionItem from a workFlow. This method is recursive and will also remove all dependent views and actionItems.
- `show` signature(object = "transformActionItem"): Print details about the object.

  t@transformationId = transformId
  t
}
cosT <- cosTransform(transformId="CosT",a=2,b=1)
summary(cosT)
A class for encapsulating a filter to be performed on transformed parameters

Description

The `transformFilter` class is a mechanism for including one or more variable transformations into the filtering process. Using a special case of `transform` we can introduce transformations inline with the filtering process eliminating the need to process `flowFrame` objects before applying a filter.

Objects from the Class

Objects of this type are not generally created “by hand”. They are a side effect of the use of the `%on%` method with a `filter` object on the left hand side and a `transformList` on the right hand side.

Slots

- `transforms`: A list of transforms to perform on the target `flowFrame`
- `filter`: The filter to be applied to the transformed frame
- `filterId`: The name of the filter (chosen automatically)

Extends

Class "filter", directly.

Examples

```r
samp <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))

## Gate this object after log transforming the forward and side scatter variables
## # Gate this object after log transforming the forward and side scatter variables
filter(samp, norm2Filter("FSC-H", "SSC-H", scale.factor=2)
  %on% transform("FSC-H"=log,"SSC-H"=log))
```
transformList-class

Class "transformList"

Description

Class "transformList"

Usage

transformList(from, tfun, to=from, transformationId = "defaultTransformation")

Arguments

from, to
Characters giving the names of the measurement parameter on which to transform on and into which the result is supposed to be stored. If both are equal, the existing parameters will be overwritten.

tfun
A list if functions or a character vector of the names of the functions used to transform the data. R’s recycling rules apply, so a single function can be given to be used on all parameters.

transformationId
The identifier for the object.

Objects from the Class

Objects can be created by calls of the form new("transformList", ...), by calling the transform method with key-value pair arguments of the form key equals character and value equals function, or by using the constructor transformList. See below for details

Slots

transforms: Object of class "list", where each list item is of class transformMap.

transformationId: Object of class "character", the identifier for the object.

Methods

colnames signature(x = "transformList"): This returns the names of the parameters that are to be transformed.

c signature(x = "transformList"): Concatenate transformLists or regular lists and transformLists.

%on% signature(e1 = "transformList", e2 = "flowFrame"): Perform a transformation using the transformList on a flowFrame or flowSet.

Author(s)

B. Ellis, F. Hahne
transformMap-class

A class for mapping transforms between parameters

Description

This class provides a mapping between parameters and transformed parameters via a function.

Objects from the Class

Objects of this type are not usually created by the user, except perhaps in special circumstances. They are generally automatically created by the inline `transform` process during the creation of a `transformFilter`, or by a call to the `transformList` constructor.

Slots

- **output**: Name of the transformed parameter
- **input**: Name of the parameter to transform
- **f**: Function used to accomplish the transform

Methods

- `show signature(object = "transformList")`: Print details about the object.

Author(s)

B. Ellis, F. Hahne

See Also

- `transform`, `transformList`

Examples

```r
new("transformMap", input="FSC-H", output="FSC-H", f=log)
```
transformReference-class

Class "transformReference"

Description

Class allowing to reference transforms, for instance as parameters.

Objects from the Class

Objects will be created internally whenever necessary and this should not be of any concern to the user.

Slots

.Data: The list of references

searchEnv: The environment into which the reference points.

transformationId: The name of the transformation

Extends

Methods

No methods defined with class "transformReference" in the signature.

Author(s)

N. Gopalakrishnan

transformView-class

Class "transformView"

Description

Class and method to capture the result of transformation operations in a flow cytometry workflow.

Usage

transformView(workflow, ID=paste("transViewRef", guid(), sep="_"), name="default", action, data)
transformView-class

Arguments

- workflow: An object of class `workFlow` for which a view is to be created.
- ID: A unique identifier of the view, most likely created by using the internal `guid` function.
- name: A more human-readable name of the view.
- data, action: References to the data and `actionItem` objects, respectively.

Value

- A reference to the `transformView` that is created inside the `workFlow` environment as a side effect of calling the `add` method.
- A `transformView` object for the constructor.

Objects from the Class

Objects should be created using the `add` method, which creates a `transformView` from a `transform` object and directly assigns it to a `workFlow`. Alternatively, one can use the `transformView` constructor function for more programmatic access.

Slots

- ID: Object of class "character". A unique identifier for the view.
- name: Object of class "character". A more human-readable name
- action: Object of class "fcActionReference". A reference to the `actionItem` that generated the view.
- env: Object of class "environment". The evaluation environment in the `workFlow`.
- data: Object of class "fcDataReference". A reference to the data that is associated to the view.

Extends

Class "view", directly.

Methods

- `Rm` signature(symbol = "transformView", envir = "workFlow", subSymbol = "character"): Remove a `transformView` from a `workFlow`. This method is recursive and will also remove all dependent views and `actionItems`.

Author(s)

Florian Hahne

See Also

- `workFlow`, `view`, `gateView`, `compensateView`, `actionItem`

Examples

- `showClass("view")`
**truncateTransform**

Create the definition of a trucate transformation function to be applied on a data set

**Description**

Create the definition of the truncate Transformation that will be applied on some parameter via the `transform` method. The definition of this function is currently \( x \{ x < a \} \leftarrow a \). Hence, all values less than \( a \) are replaced by \( a \). The typical use would be to replace all values less than 1 by 1.

**Usage**

```
truncateTransform(transformationId="defaultTruncateTransform", a=1)
```

**Arguments**

- `transformationId`
  - character string to identify the transformation
- `a`
  - double that correponds to the value at which to truncate

**Value**

Returns an object of class `transform`.

**Author(s)**

P. Haaland

**See Also**

`transform-class`, `transform`

**Examples**

```
samp <- read.FCS(system.file("extdata", "0877408774.B08", package="flowCore"))
truncateTrans <- truncateTransform(transformationId="Truncate-transformation", a=5)
dataTransform <- transform(samp, `FSC-H` = truncateTrans(`FSC-H`))
```

---

**unitytransform-class**

Class “unitytransform”

**Description**

Unity transform class transforms parameters names provided as characters into unity transform objects which can be evaluated to retrieve the corresponding columns from the data frame.
Objects from the Class

Objects can be created by calls to the constructor `unitytransform(parameters,transformationId)`.

Slots

- **Data**: Object of class "function" -flow parameters to be transformed
- **parameters**: Object of class "character" -unique ID to reference the transformation
- **transformationId**: Object of class "character" -unique ID to reference the transformation

Extends

Methods

No methods defined with class "unitytransform" in the signature.

Author(s)

Gopalakrishnan N, F.Hahne

See Also

dg1polynomial, ratio

Examples

```r
dat <- read.FCS(system.file("extdata","0877408774.B08", package="flowCore"))
un1<-unitytransform(c("FSC-H","SSC-H"),transformationId="un1")
transOut<-eval(un1)(exprs(dat))
```

view-class

Class "view"

Description

Class and method to capture the results of standard operations (called "views" here) in a flow cytometry workflow.

Usage

```r
view(workflow, ID=paste("viewRef", guid(), sep="_"),
     name="default", data, action)
```

```
parent(object)
```

```
Data(object)
```
view-class

action(object)

alias(object, ...)

Arguments

workflow An object of class workFlow for which a view is to be created.
object An object of class view or one of its subclasses.
ID A unique identifier of the view, most likely created by using the internal guid function.
name A more human-readable name of the view.
data, action References to the data and actionItem objects, respectively.
... Further arguments that get passed to the generic.

Details

Views provide a means to bind the results of standard operations on flow cytometry data in a workflow. Each view can be considered the outcome of one operation. There are more specific subclasses for the three possible types of operation: gateView for gating operations, transformView for transformations, and compensateView for compensation operations. See their documentation for details.

Value

A reference to the view that is created inside the workFlow environment as a side effect of calling the constructor.

The parent view (i.e., the view based on which the current view was created) for the parent method.

Objects from the Class

Objects should be created using the constructor view, which also assigns the view to a workFlow object.

Slots

ID: Object of class "character". A unique identifier for the view.
name: Object of class "character". A more human-readable name
action: Object of class "fcActionReference". A reference to the actionItem that generated the view.
env: Object of class "environment". The evaluation environment in the workFlow.
data: Object of class "fcDataReference". A reference to the data that is associated to the view. See gateView for details on copying and subsetting of the raw data in the context of gating.
workFlow-class

Methods

**action** signature(object = "view"): Accessor for the action slot. Note that this returns the actual actionItem object, i.e., the reference gets resolved.

**Data** signature(object = "view"): Accessor for the data slot. Note that this returns the actual data object, i.e., the reference gets resolved.

**names** signature(x = "view"): Accessor to the name slot.

**alias** signature(object = "view"): Get the alias table from a view.

**parent** signature(object = "view"): The parent view, i.e., the view based on which the current view was created.

**print** signature(x = "view"): Print details about the object.

**Rm** signature(symbol = "view", envir = "workFlow", subSymbol = "character"): Remove a view from a workFlow. This method is recursive and will also remove all dependent views and actionItems.

**show** signature(object = "view"): Print details about the object.

**xyplot** signature(x = "formula", data = "view"): Plot the data underlying the view.

**xyplot** signature(x = "view", data = "missing"): Plot the data underlying the view.

workFlow-class  
Class "workFlow"

Description

Class and methods to organize standard flow cytometry data analysis operation in a concise workflow.

Usage

workFlow(data, name = "default", env = new.env(parent = emptyenv()))

undo(wf, n=1)
**workFlow-class**

**Arguments**

- **data**: An object of class `flowFrame` or `flowSet` for which a basic view is created.
- **name**: A more human-readable name of the view.
- **env**: Object of class `environment`. The evaluation environment used for the `workFlow`.
- **wf**: Object of class `workFlow`.
- **n**: The number of operations to undo.

**Details**

*workFlow* objects organize standard flow data analysis operations like gating, compensation and transformation in one single object. The user can interact with a *workFlow* object (e.g. adding operations, removing them, summarizing the results) without having to keep track of intermediate objects and names.

The integral part of a *workFlow* is an evaluation environment which holds all objects that are created during the analysis. The structure of the whole workflow is a tree, where nodes represent links to views or results of an operation and edges represent action items or the operations themselves.

**Value**

A *workFlow* object for the constructor

Both *applyParentFilter* and *undo* are called for their side-effects.

**Objects from the Class**

Objects should be created using the constructor `workFlow`, which takes a `flowFrame` or `flowSet` as only mandatory input and creates a basic view for that.

**Slots**

- **name**: Object of class "character". The name of the workFlow object.
- **tree**: Object of class "fcTreeReference". A reference to the graphNEL objects representing the view structure of the workflow.
- **env**: Object of class "environment". The evaluation environment for the workflow in which all objects will be stored.

**Methods**

- **add** signature (wf = "workFlow", action = "concreteFilter"): Create a new `gateActionItem` and `gateView` from a `filter` and assign those to the workflow.
- **add** signature (wf = "workFlow", action = "filterList"): Create a new `gateActionItem` and `gateView` from a `filterList` and assign those to the workflow.
- **add** signature (wf = "workFlow", action = "transformList"): Create a new `transformActionItem` and `transformView` from a `transform` and assign those to the workflow.
- **add** signature (wf = "workFlow", action = "compensation"): Create a new `compensateActionItem` and `compensateView` from a `compensation` and assign those to the workflow.
assign signature(x = "ANY", value = "ANY", pos = "missing", envir = "workFlow", inherits = "missing", immediate = "missing"): Assign an object to the environment in the \texttt{workFlow} object and return a \texttt{fcReference} to it. The symbol for the object is created as a unique identifier.

assign signature(x = "missing", value = "ANY", pos = "workFlow", envir = "missing", inherits = "missing", immediate = "missing"): see above

assign signature(x = "missing", value = "ANY", pos = "missing", envir = "workFlow", inherits = "missing", immediate = "missing"): same as above, but provide custom symbol for the assignment.

assign signature(x = "character", value = "ANY", pos = "workFlow", envir = "missing", inherits = "missing", immediate = "missing"): see above

assign signature(x = "fcReference", value = "ANY", pos = "workFlow", envir = "missing", inherits = "missing", immediate = "missing"): same as above, but assign object using an existing \texttt{fcReference}. Note that assigning NULL essentially removes the original object.

[ signature(x = "workFlow", i = "ANY"): Cast a useful error message.

[ signature(x = "workFlow", i = "ANY"): Treat the \texttt{workFlow} object as a regular environment. Essentially, this is equivalent to \texttt{get(x, i)}.

$ signature(x = "workFlow", name = "character"): Allow for list-like access. Note that completion is only available for \texttt{views} since all other objects in the environment are considered to be internal.

get signature(x = "character", pos = "workFlow", envir = "missing", mode = "missing", inherits = "missing"): Get an object identified by symbol \texttt{x} from the environment in the \texttt{workFlow}.

get signature(x = "character", pos = "missing", envir = "workFlow", mode = "missing", inherits = "missing"): see above

ls signature(name = "workFlow", pos = "missing", envir = "missing", all.names = "missing", pattern = "missing"): List the content of the environment in the \texttt{workFlow}.

ls signature(name = "workFlow", pos = "missing", envir = "missing", all.names = "missing", pattern = "character"): see above

mget signature(x = "character", envir = "workFlow", mode = "missing", ifnotfound = "missing", inherits = "missing"): Get multiple objects identified by the symbols in \texttt{x} from the environment in the \texttt{workFlow}.

names signature(x = "workFlow"): List the identifiers for all \texttt{views} and \texttt{actionItems} in the \texttt{workFlow}.

plot signature(x = "workFlow", y = "missing"): Plot the structure of the \texttt{workFlow} tree.

Rm signature(symbol = "character", envir = "workFlow", subSymbol = "character"): Remove the object identified by the symbol \texttt{symbol} from the \texttt{workFlow}.

undo signature(wf = "workFlow", n = "numeric"): Undo the last \texttt{n} operations on the \texttt{workFlow}.

show signature(object = "workFlow"): Print details about the object.

summary signature(object = "workFlow"): Summarize a view in the \texttt{workFlow}.

nodes signature(object = "workFlow"): Return a named vector of node ids where the names are the human readable names stored in the alias table.
actions signature(x = "workFlow"): List the names of the actionItems in the workFlow.

views signature(x = "workFlow"): List the names of only the views in the workFlow.

alias signature(object = "workFlow"): Return the alias table for the workFlow.

alias signature(object = "environment"): Return the alias table from a generic environment. The method tries to find 'fcAliasRef' among the object symbols in the environment.

journal signature(object = "workFlow"): Return the journal for the workFlow.

journal signature(object = "environment"): Return the journal from a generic environment. The method tries to find 'fcJournalRef' among the object symbols in the environment.

tree signature(object = "workFlow"): Return the tree of the workFlow.

journal signature(object = "environment"): Return the tree from a generic environment. The method tries to find 'fcTreeRef' among the object symbols in the environment.
