Package ‘CAGEr’

December 21, 2019

Title Analysis of CAGE (Cap Analysis of Gene Expression) sequencing data for precise mapping of transcription start sites and promoterome mining

Version 1.28.0

Date 2019-10-23

Author Vanja Haberle <vanja.haberle@gmail.com>

Maintainer Vanja Haberle <vanja.haberle@gmail.com>, Charles Plessy <charles.plessy@oist.jp>, Damir Baranasic <damir.baranasic@lms.mrc.ac.uk>, Sarvesh Nikumbh <s.nikumbh@lms.mrc.ac.uk>

Description

The CAGEr package performs identification of transcription start sites and frequency of their usage from input CAGE sequencing data, normalization of raw CAGE tag count, clustering of TSSs into tag clusters (TC) and their aggregation across multiple CAGE experiments to construct the promoterome. It manipulates multiple CAGE experiments at once, performs expression profiling across experiments both at level of individual TSSs and clusters of TSSs, exports several different types of track files for visualization in the UCSC Genome Browser, performs analysis of promoter width and detects differential usage of TSSs (promoter shifting) between samples. Multicore option for parallel processing is supported on Unix-like platforms.

Author(s)

Vanja Haberle

.byCtss

Apply functions to identical CTSSes.

Description

.byCTSS is a private function using data.table objects to preform grouping operations at a high performance. These functions use non-standard evaluation in a context that raises warnings in R CMD check. By separating these functions from the rest of the code, I hope to make the workarounds easier to manage.

Usage

.byCtss(ctssDT, colName, fun)

## S4 method for signature 'data.table'
.byCtss(ctssDT, colName, fun)

Arguments

- ctssDT: A data.table representing CTSSes.
- colName: The name of the column on which to apply the function.
- fun: The function to apply.
.clusterAggregateAndSum

Aggregate identical clusters and sum their scores.

Description

Private function using data.table objects to preform grouping operations at a high performance. These functions use non-standard evaluation in a context that raises warnings in R CMD check. By separating these functions from the rest of the code, I hope to make the workarounds easier to manage.

Usage

.bandAggregateAndSum(clusters, key)

## S4 method for signature 'data.table'
.bandAggregateAndSum(clusters, key)

## S4 method for signature 'data.frame'
.bandAggregateAndSum(clusters, key)

## S4 method for signature 'GRanges'
.bandAggregateAndSum(clusters, key)

Arguments

clusters Clusters to be aggregated. data.frame, or GRanges, which will be coerced to data.frame.

key Name of the column containing the factor used to aggregate the clusters.

.get.quant.pos Get quantile positions

Description

Function that calculates position of quantiles for CTSS clusters based on distribution of tpm within the cluster.

Usage

.get.quant.pos(cumsums, clusters, q)
### Arguments

- **cumsums**: Named list of vectors containing cumulative sum for each cluster (returned by `get.cumsum` function).
- **clusters**: GRanges object representing tag clusters or consensus clusters.
- **q**: desired quantiles - single value or a vector of values.

### Value

Returns the `clusters` object with one more metadata column per value in `q`, containing Rle integers giving the relative distance of the quantile boundaries to the start position.

### Examples

```r
## Not run: #because it runs through quantilePositions() anyway.
cumsums <- CTSScumulativesTagClusters(object, 1)
clusters <- tagClustersGR(object, 1)
.get.quant.pos(cumsums, clusters, c(.1, .9))
## End(Not run)
```

### Description

Private function for normalizing CAGE tag count to a referent power-law distribution.

### Usage

```r
.powerLaw(tag.counts, fitInRange = c(10, 1000), alpha = 1.25, T = 10^6)
```

### Arguments

- **tag.counts**: Numerical values whose reverse cumulative distribution will be fitted to power-law (e.g. tag count or signal for regions, peaks, etc.)
- **fitInRange**: Range in which the fitting is done (values outside of this range will not be considered for fitting)
- **alpha**: Slope of the referent power-law distribution (the actual slope has negative sign and will be -1*alpha)
- **T**: total number of tags (signal) in the referent power-law distribution.

### Details

S4 Methods are provided for integer vectors, Rle objects, data.frame objects and DataFrame objects, so that the most complex objects can be deconstructed in simpler parts, normalized and reconstructed.
Value

Normalized values (vector of the same length as input values); i.e. what would be the value of input values in the referent distribution. Output objects are numeric, possibly Rle-encoded or wrapped in data.frames or DataFrames according to the input.

References

aggregateTagClusters  Aggregate TCs across all samples

Description

Aggregates tag clusters (TCs) across all CAGE datasets within the CAGEr object to create a referent set of consensus clusters.

Usage

aggregateTagClusters(object, tpmThreshold = 5,
  excludeSignalBelowThreshold = TRUE, qLow = NULL, qUp = NULL,
  maxDist = 100, useMulticore = FALSE, nrCores = NULL)

## S4 method for signature 'CAGEr'
aggregateTagClusters(object, tpmThreshold = 5,
  excludeSignalBelowThreshold = TRUE, qLow = NULL, qUp = NULL,
  maxDist = 100, useMulticore = FALSE, nrCores = NULL)

Arguments

object  A CAGEr object

tpmThreshold  Ignore tag clusters with normalized signal < tpmThreshold when constructing the consensus clusters.

excludeSignalBelowThreshold

When TRUE the tag clusters with normalized signal < tpmThreshold will not contribute to the total CAGE signal of a consensus cluster. When set to FALSE all TCs that overlap consensus clusters will contribute to the total signal, regardless whether they pass the threshold for constructing the clusters or not.

qLow, qUp

Set which “lower” (or “upper”) quantile should be used as 5’ (or 3’) boundary of the tag cluster. If NULL the start (for qLow) or end (for qUp) position of the TC is used.

maxDist  Maximal length of the gap (in base-pairs) between two tag clusters for them to be part of the same consensus clusters.

useMulticore  Logical, should multicore be used (supported only on Unix-like platforms).

nrCores  Number of cores to use when useMulticore = TRUE. Default (NULL) uses all detected cores.
aggregateTagClusters

Details

Since the tag clusters (TCs) returned by the `clusterCTSS` function are constructed separately for every CAGE sample within the CAGEr object, they can differ between samples in both their number, genomic coordinates, position of dominant TSS and overall signal. To be able to compare all samples at the level of clusters of TSSs, TCs from all CAGE datasets are aggregated into a single set of consensus clusters. First, TCs with signal \( \geq tpmThreshold \) from all CAGE datasets are selected, and their 5' and 3' boundaries are determined based on provided qLow and qUp parameter (or the start and end coordinates, if they are set to NULL). Finally, the defined set of TCs from all CAGE datasets is reduced to a non-overlapping set of consensus clusters by merging overlapping TCs and TCs \( \leq maxDist \) base-pairs apart. Consensus clusters represent a referent set of promoters that can be further used for expression profiling or detecting "shifting" (differentially used) promoters between different CAGE samples.

Value

For `CAGEset` objects, the `consensusClusters` slot will be populated with a data frame indicating the cluster name, chromosome, start and end coordinates, the strand, and the normalised expression score of the cluster. This table is returned by the `consensusClusters` function.

For `CAGEexp` objects, the experiment `consensusClusters` will be occupied by a `RangedSummarizedExperiment` containing the cluster coordinates as row ranges, and their expression levels in the counts and normalized assays. These genomic ranges are returned by the `consensusClustersGR` function. The CTSS ranges of the `tagCountMatrix` experiment will gain a cluster column indicating which cluster they belong to. Lastly, the number of CTSS outside clusters will be documented in the `outOfClusters` column data. This table is returned by the `consensusClusters` function.

Examples

```r
head(consensusClusters(exampleCAGEset))
aggregateTagClusters( exampleCAGEset, tpmThreshold = 50,
                      excludeSignalBelowThreshold = FALSE, maxDist = 100)
head(consensusClusters(exampleCAGEset))
aggregateTagClusters(object = exampleCAGEset, tpmThreshold = 50,
                      excludeSignalBelowThreshold = FALSE, qLow = 0.1, qUp = 0.9, maxDist = 100)
head(consensusClusters(exampleCAGEset))
consensusClustersGR(exampleCAGEexp)
aggregateTagClusters( exampleCAGEexp, tpmThreshold = 50,
                      excludeSignalBelowThreshold = FALSE, maxDist = 100)
consensusClustersGR(exampleCAGEexp)
```
aggregateTagClusters(exampleCAGEexp, tpmThreshold = 50,
  excludeSignalBelowThreshold = TRUE, maxDist = 100)
consensusClustersGR(exampleCAGEexp)

aggregateTagClusters(exampleCAGEexp, tpmThreshold = 50,
  excludeSignalBelowThreshold = TRUE, maxDist = 100,
  qLow = 0.1, qUp = 0.9)
consensusClustersGR(exampleCAGEexp)

annotateCTSS

Description

annotateCTSS annotates the CTSS of a CAGEexp object and computes annotation statistics.
annotateConsensusClusters annotates the consensus clusters of a CAGEr object.

Usage

annotateCTSS(object, ranges)
## S4 method for signature 'CAGEset,ANY'
annotateCTSS(object, ranges)
## S4 method for signature 'CAGEexp,GRanges'
annotateCTSS(object, ranges)
annotateConsensusClusters(object, ranges)
## S4 method for signature 'CAGEset,ANY'
annotateConsensusClusters(object, ranges)
## S4 method for signature 'CAGEexp,GRanges'
annotateConsensusClusters(object, ranges)

Arguments

object CAGEexp object (CAGEsets are not supported).
ranges A GRanges object, optionally containing gene_name, type and transcript_type metadata.

Value

annotateCTSS returns the input object with the following modifications:

- The Genomic Ranges of the tagCountMatrix experiment gains an annotation metadata column, with levels such as promoter, exon, intron and unknown. If the annotation has a gene_name metadata, then a genes column is also added, with gene symbols from the annotation.
• The sample metadata gets new columns, indicating total counts in each of the annotation levels. If the annotation has a gene_name metadata, then a genes column is added to indicate the number of different gene symbols detected.

annotateConsensusClusters returns the input object with the same modifications as above.

consensusClustersGR(exampleCAGEexp)

bam2CTSS

Description

Converts from BAM to CTSS

Usage

bam2CTSS(gr, removeFirstG, correctSystematicG, genome)

Arguments

gr A GRanges object returned by import.bam.
removeFirstG See getCTSS().
correctSystematicG See getCTSS().
genome See coerceInBSgenome().

Details

Converts genomic ranges representing SAM/BAM alignments into a CTSS object.
Value

Returns a CTSS object.

See Also

Other loadFileIntoGPos: import.CTSS, import.bam.ctss, import.bam, import.bedCTSS, import.bedScore, import.bedmolecule, loadFileIntoGPos, moleculesGR2CTSS

CAGEexp-class

CAGEr class to hold all data and metadata about one CAGE experiment.

Description

The CAGEr class is a MultiAssayExperiment object containing all data and metadata about a set of CAGE libraries. It is a replacement for the CAGEset class. The main difference is that the expression data is stored in DataFrame objects of Rle-encoded expression values, instead of plain dataframes. With large datasets, this saves considerable amounts of memory.

Details

If genomeName is NULL, checks of chromosome names will be disabled and G-correction will not be possible. See https://support.bioconductor.org/p/86437/ for an example on how to create a BSgenome package.

Sample labels must be syntactically valid in the sense of the make.names() function, because they will be used as column names in some tables.

Slots

metadata A list that must at least contain a genomeName member.

See Also

CAGEset, make.names

Examples

pathsToInputFiles <- list.files( system.file("extdata", package = "CAGEr") , "ctss$" , full.names = TRUE) sampleLabels <- sub( ".chr17.ctss", "", basename(pathsToInputFiles)))

# The CAGEexp object can be created using specific constructor commands
eexampleCAGEexp <-
  CAGEexp( genomeName = "BSgenome.Drerio.UCSC.danRer7" , inputFiles = pathsToInputFiles , inputFilesType = "ctss" , sampleLabels = sub( ".chr17.ctss", "", basename(pathsToInputFiles)) )

# Alternatively, it can be created just like another MultiAssayExperiment.
# This is useful when providing pre-existing colData with many columns.
CAGEr-class

CAGEr objects

Description

The **CAGEr** package provides two classes of objects to load, contain and process CAGE data:

Details

- The **CAGEset** class is the original object format in **CAGEr**, as when published in Haberle *et al.*, 2015.
- The **CAGEexp** class is a new class format in 2017, which is based on the **MultiAssayExperiment** class. In comparison with CAGEset, objects, CAGEexp objects benefit from a a more efficient data storage, using DataFrames of run-length-encoded (Rle) integers, allowing for the loading and use of much larger transcriptome datasets.

Most **CAGEr** functions support both classes interchangably, and the **CAGEr** class was created for methods that support both classes identically.

References

**CAGEr_Multicore**

**Multicore support in CAGEr**

**Description**

CAGEr is in the transition towards using the BiocParallel for multicore parallelisation. On Windows platforms, the multicore support is disabled transparently, that is, attempts to use multiple cores are silently ignored.

**Usage**

```r
CAGEr_Multicore(useMulticore = FALSE, nrCores = NULL)
```

**Arguments**

- **useMulticore**: TRUE or FALSE
- **nrCores**: number of cores to use (leave NULL to let BiocParallel choose).

**Value**

Returns either a MulticoreParam object or a SerialParam object.

**Author(s)**

Charles Plessy

**Examples**

```r
CAGEr:::CAGEr_Multicore()
CAGEr:::CAGEr_Multicore(TRUE,)
CAGEr:::CAGEr_Multicore(TRUE, 3)
CAGEr:::CAGEr_Multicore(FALSE, 3)
```

---

**CAGEset-class**

**Class** "CAGEset"

**Description**

This class is used to store one or more CAGE (Cap Analysis of Gene Expression) datasets in the form of TSSs derived from CAGE tags and frequency of their usage, and to store and extract all information generated during the workflow.

**Objects from the Class**

Objects can be created by calls of the form `new("CAGEset", ...)`.

Objects of the class contain information on the genomic coordinates of TSSs derived from sequenced CAGE tags from multiple experiments, number of tags supporting each TSS in each experiment, normalized CAGE signal at each TSS, all information on specified parameters and results of all downstream analyses. Object has to be created before reading in the data by specifying input files and their type, referent genome and labels for individual CAGE datasets, as described in the vignette. Data is read by applying a function to a created object and all further slots are filled during the workflow by applying specific functions.
Slots

gename: Object of class "character": the name of the BSgenome package used as the reference genome
inputFiles: Object of class "character": the paths to input files
inputFilesType: Object of class "character": the type of input files (e.g. bam)
sampleLabels: Object of class "character": the labels of individual CAGE experiments
librarySizes: Object of class "integer": the total number of CAGE tags per experiment
CTSScoordinates: Object of class "data.frame": the genomic coordinates of CAGE transcription start sites (CTSSs)
tagCountMatrix: Object of class "data.frame": the number of CAGE tags supporting every CTSS in each experiment
normalizedTpmMatrix: Object of class "data.frame": the normalized CAGE signal supporting every CTSS in each experiment
CTSSexpressionClusteringMethod: Object of class "character": the method used for expression clustering of CTSSs
CTSSexpressionClasses: Object of class "character": the labels of expression classes of CTSSs returned by expression clustering
clusteringMethod: Object of class "character": the method used for clustering CTSSs into tag clusters (TC)
filteredCTSSidx: Object of class "logical": the index of CTSSs included in tag clusters
tagClusters: Object of class "list": the list of tag clusters per CAGE experiment
CTSScumulativesTagClusters: Object of class "list": the cumulative distribution of CAGE signal along TCs
tagClustersQuantileLow: Object of class "list": the positions of lower quantile(s) within TCs
tagClustersQuantileUp: Object of class "list": the positions of upper quantile(s) within TCs
consensusClusters: Object of class "data.frame": the genomic coordinates of consensus clusters created by aggregating TCs across experiments
consensusClustersTpmMatrix: Object of class "matrix": the normalized CAGE signal for every consensus cluster in each experiment
consensusClustersExpressionClusteringMethod: Object of class "character" the method used for expression clustering of consensus clusters
consensusClustersExpressionClasses: Object of class "character": the labels of expression classes of consensus clusters returned by expression clustering
CTSScumulativesConsensusClusters: Object of class "list": the cumulative distribution of CAGE signal along consensus clusters
consensusClustersQuantileLow: Object of class "list": the positions of lower quantile(s) within consensus clusters
consensusClustersQuantileUp: Object of class "list": the positions of upper quantile(s) within consensus clusters
shiftingGroupX: Object of class "character": the label(s) of experiment(s) in the first shifting group
shiftingGroupY: Object of class "character": the label(s) of experiment(s) in the second shifting group
consensusClustersShiftingScores: Object of class "data.frame": the shifting scores and P-values/FDR for comparison of consensus clusters between two (groups of) experiments
Methods

**CTSSclusteringMethod** signature(object = "CAGEset"): extracts the method used for clustering CTSSs into tag clusters (TC)

**CTSScoordinates** signature(object = "CAGEset"): extracts the genomic coordinates of all CTSSs

**CTSSNormalizedTpm** signature(object = "CAGEset"): extracts the normalized CAGE signal supporting every CTSS in each experiment

**CTSSTagCount** signature(object = "CAGEset"): extracts the number of CAGE tags supporting every CTSS in each experiment

**aggregateTagClusters** signature(object = "CAGEset"): aggregates TCs across all experiments into consensus clusters

**clusterCTSS** signature(object = "CAGEset"): clusters CTSSs into TCs per experiment

**consensusClusters** signature(object = "CAGEset"): extracts the genomic coordinates and other information on consensus clusters

**consensusClustersTpm** signature(object = "CAGEset"): extracts the matrix with tpm values for consensus clusters across all samples

**cumulativeCTSSdistribution** signature(object = "CAGEset"): calculates the cumulative distribution of CAGE signal along TCs or consensus clusters

**exportCTSStoBedGraph** signature(object = "CAGEset"): creates bedGraph files of CTSSs for visualization in the UCSC Genome Browser

**exportToBed** signature(object = "CAGEset"): creates various types of BED files for visualization in the UCSC Genome Browser

**expressionClasses** signature(object = "CAGEset"): extracts the labels of the expression classes of CTSSs or consensus clusters returned from expression profiling

**extractExpressionClass** signature(object = "CAGEset"): extracts CTSSs or consensus clusters belonging to specified expression class

**genomeName** signature(object = "CAGEset"): extracts the name of the BSgenome package used as the referent genome

**getCTSS** signature(object = "CAGEset"): reads in specified input files and fills in information on detected CTSSs and their tag count

**getExpressionProfiles** signature(object = "CAGEset"): performs expression clustering of CTSSs or consensus clusters across experiments

**getShiftingPromoters** signature(object = "CAGEset"): extracts consensus clusters with shifting score and/or FDR above specified threshold

**inputFiles** signature(object = "CAGEset"): extracts the paths of input CAGE data files

**inputFilesType** signature(object = "CAGEset"): extracts the type of input CAGE data files

**librarySizes** signature(object = "CAGEset"): extracts the library sizes of individual CAGE experiments within CAGEset object

**mergeSamples** signature(object = "CAGEset",mergeIndex = "numeric"): merges specified experiments (samples) into one (e.g. replicas)

**normalizeTagCount** signature(object = "CAGEset"): normalizes raw CAGE tag count

**plotCorrelation** signature(object = "CAGEset"): plots pairwise scatter plots and calculates correlation between samples

**plotExpressionProfiles** signature(object = "CAGEset"): creates file with beanplots of expression across experiments for CTSSs or consensus clusters belonging to different expression classes
plotInterquantileWidth signature(object = "CAGEset"): creates file with histograms of interquantile width

plotReverseCumulatives signature(object = "CAGEset"): creates file with reverse cumulative plots of CAGE tag count per CTSS

quantilePositions signature(object = "CAGEset"): calculates the positions of specified quantiles within TCs or consensus clusters

sampleLabels signature(object = "CAGEset"): extracts the labels of individual CAGE experiments within CAGEset object

scoreShift signature(object = "CAGEset", groupX = "character", groupY = "character"): calculates the shifting score and tests the statistical significance of differential TSS usage for consensus clusters between two specified (groups of) samples

setColors signature(object = "CAGEset"): assigns color to each sample to be used in visualisation

show signature(object = "CAGEset"): displays CAGEset object in a user friendly way

tagClusters signature(object = "CAGEset"): extracts the tag clusters for specified CAGE experiment

Coercion

as(from, "CAGEset"): Creates a CAGEset object from a data.frame object.

Author(s)

Vanja Haberle

Examples

showClass("CAGEset")
# S4 method for signature 'CAGEexp'
clusterCTSS(object, threshold = 1, nrPassThreshold = 1, thresholdIsTpm = TRUE, method = c("distclu", "paraclu", "custom"), maxDist = 20, removeSingletons = FALSE, keepSingletonsAbove = Inf, minStability = 1, maxLength = 500, reduceToNonoverlapping = TRUE, customClusters = NULL, useMulticore = FALSE, nrCores = NULL)

## Arguments

### object
A CAGEr object.

### threshold, nrPassThreshold
Ignore CTSSs with signal < threshold in < nrPassThreshold experiments.

### thresholdIsTpm
Logical indicating if threshold is expressed in raw tag counts (FALSE) or normalized signal (TRUE).

### method
Method to be used for clustering: "distclu", "paraclu" or "custom". See Details.

### maxDist
Maximal distance between two neighbouring CTSSs for them to be part of the same cluster. Used only when method = "distclu", otherwise ignored.

### removeSingletons
Logical indicating if tag clusters containing only one CTSS be removed. Ignored when method = "custom".

### keepSingletonsAbove
Controls which singleton tag clusters will be removed. When removeSingletons = TRUE, only singletons with signal < keepSingletonsAbove will be removed. Useful to prevent removing highly supported singleton tag clusters. Default value Inf results in removing all singleton TCs when removeSingletons = TRUE. Ignored when method = "custom".

### minStability
Minimal stability of the cluster, where stability is defined as ratio between maximal and minimal density value for which this cluster is maximal scoring. For definition of stability refer to Frith et al., Genome Research, 2007. Clusters with stability < minStability will be discarded. Used only when method = "paraclu".

### maxLength
Maximal length of cluster in base-pairs. Clusters with length > maxLength will be discarded. Ignored when method = "custom".

### reduceToNonoverlapping
Logical, should smaller clusters contained within bigger cluster be removed to make a final set of tag clusters non-overlapping. Used only method = "paraclu".

### customClusters
Genomic coordinates of predefined regions to be used to segment the CTSSs. The format is either a GRanges object or a data.frame with the following columns: chr (chromosome name), start (0-based start coordinate), end (end coordinate), strand (either "+", or "+") . Used only when method = "custom".

### useMulticore
Logical, should multicore be used. useMulticore = TRUE has no effect on non-Unix-like platforms.

### nrCores
Number of cores to use when useMulticore = TRUE. Default value NULL uses all detected cores.
clusterCTSS

Details
The "distclu" method is an implementation of simple distance-based clustering of data attached to sequences, where two neighbouring TSSs are joined together if they are closer than some specified distance (see distclu-functions for implementation details.

"paraclu" is an implementation of Paraclu algorithm for parametric clustering of data attached to sequences (Frith et al., Genome Research, 2007). Since Paraclu finds clusters within clusters (unlike distclu), additional parameters (removeSingletons, keepSingletonsAbove, minStability, maxLength and reduceToNonoverlapping) can be specified to simplify the output by discarding too small (singleton) or too big clusters, and to reduce the clusters to a final set of non-overlapping clusters.

Clustering is done for every CAGE dataset within the CAGEr object separately, resulting in a different set of tag clusters for every CAGE dataset. TCs from different datasets can further be aggregated into a single referent set of consensus clusters by calling the aggregateTagClusters function.

Value
The slots clusteringMethod, filteredCTSSidx and tagClusters of the provided CAGEset object will be occupied by the information on method used for clustering, CTSSs included in the clusters and list of tag clusters per CAGE experiment, respectively. To retrieve tag clusters for individual CAGE dataset use the tagClusters() function.

In CAGEexp objects, the results will be stored as a GRangesList of TagClusters objects in the metadata slot tagClusters. The TagClusters objects will contain a filteredCTSSidx column if appropriate. The clustering method name is saved in the metadata slot of the GRangesList.

coorceInBSgenome

coorceInBSgenome

---

**Description**
A private (non-exported) function to discard any range that is not compatible with the CAGEr object's BSgenome.

**Usage**

coerceInBSgenome(gr, genome)

**Arguments**

- **gr**
  - The genomic ranges to coerce.

- **genome**
  - The name of a BSgenome package, which must me installed, or NULL to skip coercion.

**Value**
A GRanges object in which every range is guaranteed to be compatible with the given BSgenome object. The sequnames of the GRanges are also set accordingly to the BSgenome.

---

**consensusClusterConvertors**

Private functions to convert CC formats

---

**Description**
Interconvert consensus clusters (CC) formats used in classes CAGEset (data.frame) and CAGEexp (GRanges).

**Usage**

CCgranges2dataframe(gr)

CCdataframe2granges(df)

**Arguments**

- **gr**
  - Consensus clusters in GRanges format.

- **df**
  - Consensus clusters in data.frame format.
consensusClusters <-

Other df2granges converters: tagClusterConvertors

Examples

df <- consensusClusters(exampleCAGEset)
head(df)
gr <- CCdataframe2granges(df)
gr
# No round-trip because start and end were not integer in df.
# identical(df, CCgranges2dataframe(gr))

consensusClusters<-  Set consensus clusters from CAGEr objects

Description

Set the information on consensus clusters in a CAGEr object.

Usage

consensusClusters(object) <- value
## S4 replacement method for signature 'CAGEset'
consensusClusters(object) <- value
## S4 replacement method for signature 'CAGEexp'
consensusClusters(object) <- value
consensusClustersSE(object) <- value
## S4 replacement method for signature 'CAGEset,ANY'
consensusClustersSE(object) <- value
## S4 replacement method for signature 'CAGEexp,RangedSummarizedExperiment'
consensusClustersSE(object) <- value
consensusClustersGR(object) <- value
## S4 replacement method for signature 'CAGEset'
consensusClustersGR(object) <- value
## S4 replacement method for signature 'CAGEexp'
consensusClustersGR(object) <- value

Arguments

object A CAGEr object.
value A data.frame of consensus clusters
consensusClustersDESeq2

Details
These setter methods are mostly for internal use, but are exported in case they may be useful to advanced users.

Author(s)
Vanja Haberle
Charles Plessy

consensusClustersDESeq2

Export consensus cluster expression data for DESeq2 analysis

Description
Creates a DESeqDataSet using the consensus cluster expression data in the experiment slot consensusClusters and the sample metadata of the CAGEexp object. The formula must be built using factors already present in the sample metadata.

Usage
consensusClustersDESeq2(object, design)

## S4 method for signature 'CAGEset'
consensusClustersDESeq2(object, design)

## S4 method for signature 'CAGEexp'
consensusClustersDESeq2(object, design)

Arguments

object A CAGEexp object.
design A formula for the DESeq2 analysis.

Author(s)
Charles Plessy

See Also
DESeqDataSet in the DESeq2 package.
Other CAGEr clusters functions: CTSSclusteringMethod, CTSScumulativesTagClusters, CustomConsensusClusters, aggregateTagClusters, clusterCTSS, consensusClustersGR, cumulativeCTSSdistribution, plotInterquantileWidth, quantilePositions, tagClusters

Examples

exampleCAGEexp$group <- c("a", "a", "b", "b", "a")
consensusClustersDESeq2(exampleCAGEexp, ~group)
consensusClustersGR  
Get consensus clusters from CAGEr objects

Description
Extracts the information on consensus clusters from a CAGEr object.

Usage

```r
consensusClustersGR(object, sample = NULL, 
                    returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)
## S4 method for signature 'CAGEset'
consensusClustersGR(object, sample = NULL, 
                    returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)
## S4 method for signature 'CAGEexp'
consensusClustersGR(object, sample = NULL, 
                    returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

consensusClustersSE(object)
## S4 method for signature 'CAGEset'
consensusClustersSE(object)
## S4 method for signature 'CAGEexp'
consensusClustersSE(object)

consensusClusters(object, sample = NULL, 
                    returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)
## S4 method for signature 'CAGER'
consensusClusters(object, sample = NULL, 
                    returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)
```

Arguments

- **object**
  A CAGEr object.

- **sample**
  Optional. Label of the CAGE dataset (experiment, sample) for which to extract sample-specific information on consensus clusters.

- **returnInterquantileWidth**
  Should the interquantile width of consensus clusters in specified sample be returned. Used only when `sample` argument is specified, otherwise ignored.

- **qLow, qUp**
  Position of which quantile should be used as a left (lower) or right (upper) boundary when calculating interquantile width. Used only when `sample` argument is specified and `returnInterquantileWidth = TRUE`, otherwise ignored.

Value

consensusClustersGR returns a ConsensusClusters object, which is a GRanges wrapper containing similar information as the data frame returned by consensusClustersGR. The score columns
consensusClustersQuantile

indicates the normalised expression value of each cluster, either across all samples (sample = NULL), or for the selected sample. The tpm column provides the same information for compatibility with CAGEset objects but may be removed in the future.

consensusClustersSE returns the SummarizedExperiment stored in the consensusClusters experiment slot of the CAGEexp object.

consensusClusters returns a data.frame with information on consensus clusters, including genomic coordinates. When sample argument is NOT specified, total CAGE signal across all CAGE datasets (samples) is returned in the tpm column. When sample argument is specified, the tpm column contains CAGE signal of consensus clusters in that specific sample. When returnInterquantileWidth = TRUE, additional sample-specific information is returned, including position of the dominant TSS, and interquantile width of the consensus clusters in the specified sample.

-----------------------------------------------------------------------------------

consensusClustersQuantile

Quantile metadata stored in CAGEr objects.

Description

Accessors for consensus cluster quantile data in CAGEr objects.
Usage

consensusClustersQuantileLow(object, samples = NULL)

## S4 method for signature 'CAGEset'
consensusClustersQuantileLow(object, samples = NULL)

## S4 method for signature 'CAGEexp'
consensusClustersQuantileLow(object, samples = NULL)

consensusClustersQuantileUp(object, samples = NULL)

## S4 method for signature 'CAGEset'
consensusClustersQuantileUp(object, samples = NULL)

## S4 method for signature 'CAGEexp'
consensusClustersQuantileUp(object, samples = NULL)

consensusClustersQuantile(object, sample = NULL, q)

## S4 method for signature 'CAGEset'
consensusClustersQuantile(object, sample = NULL, q)

## S4 method for signature 'CAGEexp'
consensusClustersQuantile(object, sample = NULL, q)

consensusClustersQuantileLow(object, samples = NULL) <- value

## S4 replacement method for signature 'CAGEset'
consensusClustersQuantileLow(object, samples = NULL) <- value

consensusClustersQuantileUp(object, samples = NULL) <- value

## S4 replacement method for signature 'CAGEset'
consensusClustersQuantileUp(object, samples = NULL) <- value

Arguments

object A CAGEr object.
samples Sample name(s), number(s) or NULL (default) for all samples.
sample A single sample name or number, or NULL (default) for all samples.
q A quantile.
value A list (one entry per sample) of data frames with multiple columns: cluster for the cluster ID, and then q_0.n where 0.n indicates a quantile.
## consensusClustersTpm

### Extracting consensus clusters tpm matrix from CAGEset object

**Description**

Extracts a table with normalized CAGE tag values for consensus clusters across all samples from a CAGEr object.

**Usage**

```r
consensusClustersTpm(object)
```

**Arguments**

- `object` A CAGEr object.

**Value**

Returns the matrix of normalized expression values of CAGE clusters across all samples.

**Author(s)**

Vanja Haberle

**See Also**

- `consensusClusters`

**Examples**

```r
head(consensusClustersTpm(exampleCAGEset))
head(consensusClustersTpm(exampleCAGEexp))
```

---

### coverage-functions

**Private functions behind cumulativeCTSSdistribution**

**Description**

`.getCumsum` calculates cumulative sums of tpm along the clusters.
Usage

.getCAGEsignalCoverage(ctss.chr, clusters)
.getCumsumChr2(clusters, ctss, chrom, str)
.getCumsum(ctss, clusters, useMulticore = FALSE, nrCores = NULL)

Arguments

tcss.chr A 'CTSS.chr" object (guaranteed to have only one chromosome).
clusters GRanges as per tagClustersGR().
tcss GRanges as per CTSScoordinatesGR, with the score of one sample.
chrom a chromosome name
str a strand name
useMulticore, nrCores See clusterCTSS.

Details

'.getCAGEsignalCoverage" does... Note that strand is not taken into account.

.getCumsumChr2

Value

.getCumsum returns a list of Rle vectors (IRanges package) containing cumulative sum for each cluster (length of list is equal to number of clusters and names of the list components corespond to the name of the corresponding cluster) v.

Examples

library(GenomicRanges)
library(IRanges)
crss <- CAGEr:::.CTSS(GPos( stitch = FALSE
   , GRanges( sequename=Rle("chr1")
      , IRanges(c(1,3,4,12,14,25,28,31,35), w=1)
      , strand = "+")
   , score(ctss) <- 1
ctss.chr <- CAGEr:::.CTSS.chr(ctss)
clusters <- GRanges( sequename = Rle("chr1")
   , ranges = IRanges(c(1,12,25,31,32), c(4,14,28,31,33))
   , strand = "+")
chrom <- "chr1"
str <- "+
CAGEr:::.getCAGEsignalCoverage(ctss.chr, clusters)
CAGEr:::.getCumsumChr2(clusters, ctss, chrom, str)
crss <- CTSSnormalizedTpmGR(exampleCAGEset, "sample1")
crss <- ctss[ctss$filteredCTSSidx]
clusters <- tagClustersGR(exampleCAGEset, "sample1")
clusters.cumsum <- RleList(CAGEr:::.getCumsum(ctss, clusters))
identical(lapply(exampleCAGEset@CTSScumulativesTagClusters[[1]],decode)
   , lapply(clusters.cumsum, decode))
# Not identical if not decoded because Rle method is attached to S4Vectors in one case
CTSS-class

# and to IRanges in the other case.
decode(clusters.cumsum[[1]])
ctss[queryHits(findOverlaps(ctss, clusters[1]))]
custers[1]

csss <- CTSSnormalizedTpmGR(exampleCAGEexp, "Zf.30p.dome")
csss <- ctss[ctss$filteredCTSSidx]
clusters <- tagClustersGR(exampleCAGEexp, "Zf.30p.dome")
clusters.cumsum <- CAGEr:::.getCumsum(ctss, head(clusters))
decode(clusters.cumsum[[3]])
ctss[queryHits(findOverlaps(ctss, clusters[3]))]
custers[3]

CTSS-class

Classes for type safety.

Description

The CTSS class represents CAGE transcription start sites (CTSS) at single-nucleotide resolution, using GPos as base class. It is used internally by CAGEr for type safety.

The ConsensusClusters class represents consensus clusters. It is used internally by CAGEr for type safety.

Details

The genomeName element of the metadata slot is used to store the name of the BSgenome package used when constructing the CAGEr object. Be careful that calling the CTSS constructor twice in a row will erase the fist metadata (because the GPos constructor does so). CAGEr uses the UnstitchedGPos implementation of GPos.

The CTSS.chr class represents a CTSS object that is guaranteed to be only on a single chromosome. It is used internally by CAGEr for type safety.

Consensus clusters must not overlap, so that a single TSS in the genome can only be attributed to a single cluster.

The TagClusters class represents tag clusters. It is used internally by CAGEr for type safety.

Author(s)

Charles Plessy

Examples

csss <- CAGEr:::.CTSS( CTSScoordinatesGR(exampleCAGEexp),
    , bsgenomeName = genomeName(exampleCAGEexp))
genomeName(csss)

csss.chr <- as(CTSScoordinatesGR(exampleCAGEexp), "CTSS.chr")
CTSSclusteringMethod  Get/set CTSS clustering method

Description
Returns or sets the name of the method that was used make tag clusters from the CTSSs of a CAGEr object.

Usage
CTSSclusteringMethod(object)

## S4 method for signature 'CAGEset'
CTSSclusteringMethod(object)

## S4 method for signature 'GRangesList'
CTSSclusteringMethod(object)

## S4 method for signature 'CAGEexp'

```

CTSStagCountSE(object) <- value

```r
## S4 replacement method for signature 'CAGEset'
CTSStagCountSE(object) <- value
```

```r
## S4 replacement method for signature 'CAGEexp'
CTSStagCountSE(object) <- value
```

**Arguments**

- **object**  
  A CAGEset or CAGEexp object.

- **value**  
  Coordinates to update, in a format according to the function name.
**CTSScumulativesTagClusters**

**Value**

`CTSScoordinates()` returns a `data.frame` with genomic coordinates of all TSSs. The `pos` column contains 1-based coordinate of the TSS.

`CTSScoordinatesGR` returns the coordinates as a `CTSS()` object wrapping genomic ranges. A filtered `CTSSidx` column metadata will be present if `clusterCTSS()` was ran earlier.

## S4 method for signature 'CAGEexp'
CTSSnormalizedTpmDF(object)

CTSSnormalizedTpmGR(object, samples)

## S4 method for signature 'CAGEr'
CTSSnormalizedTpmGR(object, samples)

### Arguments

- **object**: A CAGEset or CAGEexp object.
- **samples**: The name of sample(s) as reported by sampleLabels(object), or the number identifying the sample(s).

### Value

- **CTSSnormalizedTpm**: returns a data.frame containing coordinates and normalized CAGE signal supporting each TSS (rows) in every CAGE dataset (columns).
- **CTSSnormalizedTpmDF**: returns a data.frame of normalised expression values.
- **CTSSnormalizedTpmDF**: returns a DataFrame of normalised expression values.

```
CTSStagCount

Extract raw CAGE TSSs expression tables from CAGER objects

Description

Extracts the tag count for all detected TSSs in all CAGE datasets from CAGEset and CAGEexp objects.

Usage

CTSStagCount(object)

## S4 method for signature 'CAGEset'
CTSStagCount(object)

## S4 method for signature 'CAGEexp'
CTSStagCount(object)

CTSStagCountDf(object)

## S4 method for signature 'CAGEset'

CTSStagCountDF(object)

## S4 method for signature 'CAGEset'
CTSStagCountDF(object)

## S4 method for signature 'CAGEexp'
CTSStagCountDF(object)

CTSStagCountDA(object)

## S4 method for signature 'CAGER'
CTSStagCountDA(object)

CTSStagCountGR(object, samples)

## S4 method for signature 'CAGER'
CTSStagCountGR(object, samples)

CTSStagCountSE(object)

Arguments

object       A CAGER object.
samples     (For CTSStagCountGR.) Name(s) or number(s) identifying sample(s).
### Value

Returns an object with number of CAGE tags supporting each TSS (rows) in every CAGE dataset (columns). The class of the object depends on the function being called:

- **CTSStagCount**: A data.frame, containing coordinates and expression values.
- **CTSStagCountDF**: A `data.frame`, containing only expression values.
- **CTSStagCountDF**: A `DataFrame` of Rle integers.
- **CTSStagCountDA**: A `DelayedArray` wrapping a `DataFrame` of Rle integers.
- **CTSStagCountSE**: A `RangedSummarizedExperiment` containing a `DataFrame` of Rle integers.
- **CTSStagCountGR**: A CTS object (wrapping GRanges) containing a score column indicating expression values for a given sample.

- `getCTSS()`

Other CAGEr accessor methods: `CTSSclusteringMethod`, `CTSScoordinates`, `CTSScumulatesTagClusters`, `CTSSnormalizedTpms`, `CTSStagCountTable`, `GeneExpDESeq2`, `GeneExpSE`, `consensusClustersGR`, `genomeName`, `inputFilesType`, `inputFiles`, `librarySizes`, `sampleLabels`, `seqNameTotalsSE`, `tagClusters`

### Examples

```r
head(CTSStagCount(exampleCAGEset))
head(CTSStagCountDF(exampleCAGEset))
CTSStagCountDF(exampleCAGEset)
CTSStagCountDA(exampleCAGEset)

head(CTSStagCount(exampleCAGEexp))
head(CTSStagCountDF(exampleCAGEexp))
CTSStagCountDF(exampleCAGEexp)
CTSStagCountDA(exampleCAGEexp)
```
Usage

```r
CTSStagCountTable(object)
```

## S4 method for signature 'CAGEset'

```r
CTSStagCountTable(object)
```

## S4 method for signature 'CAGEexp'

```r
CTSStagCountTable(object)
```

## S4 method for signature 'CAGEset'

```r
CTSStagCountSE(object)
```

## S4 method for signature 'CAGEexp'

```r
CTSStagCountSE(object)
```

Arguments

- `object` A CAGEset or CAGEexp object.

Value

Returns an expression table with the number of CAGE tags supporting each TSS (rows) in every CAGE dataset (columns). The table is in `data.frame` format for CAGEset objects and in `DataFrame` format for CAGEexp objects. Use this function when the next consumer can handle both formats.

Author(s)

Vanja Haberle

```r
tagCount <- CTSStagCount(exampleCAGEset)
head(tagCount)
```

CTSStoGenes

Make a gene expression table.

Description

Add a gene expression table in the GeneExpSE experiment slot of an annotated CAGEexp object. CAGEset objects are not supported.
Usage

CTSStoGenes(object)

## S4 method for signature 'CAGEset'
CTSStoGenes(object)

## S4 method for signature 'CAGEexp'
CTSStoGenes(object)

Arguments

object  A CAGEexp object that was annotated with the annotateCTSS() function.

Value

The input object with the following modifications:

- A new geneExpMatrix experiment containing gene expression levels as a SummarizedExperiment object with one assay called counts, which is plain matrix of integers. (This plays better than Rle DataFrames when interfacing with downstream packages like DESeq2, and since the number of genes is limited, a matrix will not cause problems of performance.)
- New genes column data added, indicating total number of gene symbols detected per library.
- New unannotated column data added, indicating for each sample the number of counts that did not overlap with a known gene.

cumulativeCTSSdistribution

Cumulative sums of CAGE counts along genomic regions

Description

Calculates the cumulative sum of raw CAGE counts along each tag cluster or consensus cluster in every sample within a CAGEr object.

Usage

cumulativeCTSSdistribution(object, clusters = c("tagClusters", "consensusClusters"), useMulticore = FALSE, nrCores = NULL)

## S4 method for signature 'CAGEr'
cumulativeCTSSdistribution(object,
  clusters = c("tagClusters", "consensusClusters"),
  useMulticore = FALSE, nrCores = NULL)

Arguments

object
  A CAGEr object

clusters
tagClusters or consensusClusters.

useMulticore
  Logical, should multicore be used. useMulticore = TRUE has no effect on non-Unix-like platforms.

nrCores
  Number of cores to use when useMulticore = TRUE (set to NULL to use all detected cores).

Value

For CAGEset objects, the slot CTSScumulativesTagClusters (when clusters = "tagClusters") or CTSScumulativesConsensusClusters (when clusters = "consensusClusters") of the will be occupied by the list containing cumulative sum of the CAGE signal along genomic regions per CAGE experiment. In CAGEexp objects, cumulative sums are stored in the metadata slot using the RleList class.

cumulativeCTSSdistribution(exampleCAGEexp, clusters = "consensusClusters")

CustomConsensusClusters

Expression levels of consensus cluster

Description

Intersects custom consensus clusters with the CTSS data in a CAGEexp object, and stores the result
as a expression matrices (raw and normalised tag counts).

Usage

CustomConsensusClusters(object, clusters, threshold = 0,
nrPassThreshold = 1, thresholdIsTpm = TRUE)

## S4 method for signature 'CAGEexp,GRanges'
CustomConsensusClusters(object, clusters,
 threshold = 0, nrPassThreshold = 1, thresholdIsTpm = TRUE)

Arguments

object A CAGEexp object
clusters Consensus clusters in GRanges format.
threshold, nrPassThreshold
Only CTSSs with signal >= threshold in >= nrPassThreshold experiments
will be used for clustering and will contribute towards total signal of the cluster.
thresholdIsTpm Logical, is threshold raw tag count value (FALSE) or normalized signal (TRUE).

Details

Consensus clusters must not overlap, so that a single base of the genome can only be attributed to a
single cluster. This is enforced by the .ConsensusClusters constructor.

Value

stores the result as a new RangedSummarizedExperiment in the experiment slot of the object. The
assays of the new experiment are called counts and normalized. An outOfClusters column is
added to the sample metadata to reflect the number of molecules that do not have their TSS in a
consensus cluster.

---

distclu-functions

Private functions for distance clustering.

Description

The flow of data is that a CTSS object of CTSSes is progressively deconstructed, and data to form the clusters is progressively integrated in a data.table object, which is finally converted to GRanges at the end. Doing the whole clustering with GRanges is more elegant, but looping on a GRangesList was just too slow. Maybe the operation on the data.table is more efficient because it is vectorised.

`.cluster.ctss.strand` does the strandless distance clustering of strandless CTSS positions from a single chromosome. Input does not need to be sorted, but pay attention that the output is sorted.

`.cluster.ctss.chr` does the stranded distance clustering of CTSS on a single chromosome, by dispatching both strands to `.cluster.ctss.strand` and merging the results, taking care keep the cluster IDs unique. Be careful that this function does not look at the score.

.ctss2clusters` does the stranded distance clustering of CTSS.

.summarize.clusters calculates the number of CTSS, and the position and score of a main peak, for each cluster.

.distclu receives the data from the main clusterCTSS and dispatches each for (possibly parallel) processing.

Usage

`.cluster.ctss.strand(ctss.ipos.chr, max.dist)`

`.cluster.ctss.chr(ctss.chr, max.dist)`

.ctss2clusters(ctss, max.dist = 20, useMulticore = FALSE, nrCores = NULL)

.summarize.clusters(ctss.clustered, removeSingletons = FALSE, keepSingletonsAbove = Inf)
.distclu(se, max.dist = 20, removeSingletons = FALSE, keepSingletonsAbove = Inf, useMulticore = FALSE, nrCores = NULL)

Arguments

crss.ipos.chr  A IPos object.
max.dist       See clusterCTSS().
css.chr        A CTSS.chr object.
css            A CTSS object with a score column.
useMulticore, nrCores See clusterCTSS.
css.clustered  A data.table object representing the cluster ID (id), chromosome coordinates (chr, pos, strand) and the score of each CTSS.
removeSingletons Remove "singleton" clusters that span only a single nucleotide? (default = FALSE).
keepSingletonsAbove Even if removeSingletons = TRUE, keep singletons when their score is above threshold (default = Inf).
se              A SummarizedExperiment object representing the CTSSes and their expression in each sample.

Value

.distcluster.strand returns an data.table object containing arbitrary cluster IDs (as integers) for each CTSS.
distcluster.chr returns a data.table object representing the chromosome coordinates (chr, pos, strand) of each CTSS, with their cluster ID (id).
css2clusters returns a data.table object representing the cluster ID (id), chromosome coordinates (chr, pos, strand) and the score of each CTSS.
.summarize.clusters returns GRanges describing the clusters.
distclu returns GRanges describing the clusters.

Examples

# Get example data
library(IRanges)
library(GenomicRanges)

#.cluster.ctss.strand
css.ipos.chr <- IPos(c(1,3,4,12,14,25,28))

## End(Not run)

data(exampleCAGEset)

Description

This is a CAGEset object that contains CAGE data for part of chromosome 13 from five different zebrafish (Danio rerio) samples. It is intended to be used as an input data in running examples from CAGER package help pages.

Usage

data(exampleCAGEset)

Format

A CAGEset object

Examples

eampleCAGEset
Example zebrafish annotation data

Description

Annotation data for zebrafish’s chromosome 17’s interval 26000000-54000000 (Zv9/danRer7 genome), to be used in documentation examples.

Usage

exampleZv9_annot

Format

An object of class GRanges of length 7467.

Details

Data was retrieved from ENSEMBL’s Biomart server using a query to extract gene, transcripts and exon coordinates. For the record, here it is as URL (long, possibly overflowing).

http://mar2015.archive.ensembl.org/biomart/martview/78d86c1d6b4ef51568ba6d46f7d8b2547VIRTUALSCHEMAANNOTATION

And here it is as XML.

```xml
<Query virtualSchemaName = "default" formatter = "TSV" header = "0" uniqueRows = "0" count = "" datasetConfigVersion = "0.6" >
    <Dataset name = "drerio_gene_ensembl" interface = "default" >
        <Attribute name = "ensembl_gene_id" />
        <Attribute name = "ensembl_transcript_id" />
        <Attribute name = "start_position" />
        <Attribute name = "end_position" />
        <Attribute name = "transcript_start" />
        <Attribute name = "transcript_end" />
        <Attribute name = "strand" />
        <Attribute name = "chromosome_name" />
        <Attribute name = "external_gene_name" />
        <Attribute name = "gene_biotype" />
        <Attribute name = "exon_chrom_start" />
        <Attribute name = "exon_chrom_end" />
        <Attribute name = "is_constitutive" />
        <Attribute name = "rank" />
    </Dataset>
</Query>
```

The downloaded file was then transformed as follows.

```r
x <- read.delim("~/Downloads/mart_export.txt", stringsAsFactors = FALSE)
e <- GRanges(paste0("chr", x$Chromosome.Name), IRanges(x$Exon.Chr.Start..bp., x$Exon.Chr.End..bp.))
e$gene_name <- Rle(x$Associated.Gene.Name)
e$transcript_type <- Rle(x$Gene.type)
```
exportCTSStoBedGraph

```r
# Set exon type
etype <- "exon"
eterle <- etype

e <- GRanges(paste0("chr", x$Chromosome.Name), IRanges(x$Exon.Chr.Start..bp., x$Exon.Chr.End..bp.),
           e$gene_name <- Rle(x$Associated.Gene.Name)
e$transcript_type <- Rle(x$Gene.type)
e$type <- "exon"
eterle <- etype
e <- sort(unique(e))

# Set gene type

g <- GRanges( paste0("chr", x$Chromosome.Name), IRanges(x$Gene.Start..bp., x$Gene.End..bp.),
          g$gene_name <- Rle(x$Associated.Gene.Name)
g$transcript_type <- Rle(x$Gene.type)
g$type <- "gene"
g <- sort(unique(g))

# Set transcript type

t <- GRanges( paste0("chr", x$Chromosome.Name), IRanges(x$Transcript.Start..bp., x$Transcript.End..bp.),
             t$gene_name <- Rle(x$Associated.Gene.Name)
t$transcript_type <- Rle(x$Gene.type)
t$type <- "transcript"
t <- sort(unique(t))

gff <- sort(c(g, t, e))
gff <- gff[seqnames(gff) == "chr17"]
gff <- gff[start(gff) > 26000000 & end(gff) < 54000000]
seqlevels(gff) <- seqlevelsInUse(gff)
save(gff, "data/exampleZv9_annot.RData", compress = "xz")
```

exportCTSStoBedGraph Creating bedGraph/bigWig tracks of CAGE transcription starts sites

Description
Creates bedGraph or BigWig file(s) with track(s) of CAGE signal supporting each TSS that can be visualised in the UCSC Genome Browser.
exportCTSStoBedGraph

Usage

```
exportCTSStoBedGraph(object, values = "normalized", format = "BigWig", oneFile = TRUE)
```

## S4 method for signature 'CAGEr'
exportCTSStoBedGraph(object, values = "normalized", format = "BigWig", oneFile = TRUE)

Arguments

- **object**: A CAGEr object.
- **values**: Specifies which values will be exported to the bedGraph file. Can be either "raw" to export raw tag count values or "normalized" to export normalized values.
- **format**: The format of the output.
- **oneFile**: Logical, should all CAGE datasets be exported as individual tracks into the same bedGraph file (TRUE) or into separate bedGraph files (FALSE). Used only when format="bedGraph", otherwise ignored.

Value

Creates bedGraph or BigWig file(s) in the working directory that can be directly visualised as custom tracks in the UCSC Genome Browser. If format="bedGraph" and oneFile = TRUE one bedGraph file containing multiple annotated tracks will be created, otherwise two files per CAGE dataset will be created, one for plus strand and one for minus strand CTSSs, and they will be named according to the labels of individual datasets. All bedGraph files contain headers with track description and can be directly uploaded as custom tracks to the UCSC Genome Browser.

When format="bigWig", two binary BigWig files per CAGE dataset are created, one for plus strand and one for minus strand CTSSs. Since BigWig files cannot contain headers with track description, a separate file named "CTSS.normalized.all.samples.track.description.txt" is created, which contains track headers for all BigWig files. To use these headers for adding custom tracks to the UCSC Genome Browser, move the BigWig files to a web location and edit the bigDataUrl sections in the headers file to point to corresponding BigWig files.

- normalizeTagCount
- Other CAGEr export functions: exportToBed

Examples

```
exportCTSStoBedGraph(exampleCAGEset, values = "normalized", format = "bedGraph", oneFile = TRUE)
exportCTSStoBedGraph(exampleCAGEset, values = "normalized", format = "BigWig", oneFile = TRUE)
```
**exportToBed**

*Create BED tracks of TSSs and clusters of TSSs*

**Description**

Creates BED file(s) with track(s) of individual CTSSs, tag clusters or consensus clusters. CTSSs and consensus clusters can be optionally colored in the color of their expression class. *Tag clusters* and *consensus clusters* can be displayed in a gene-like representation with a line showing full span on the cluster, filled block showing interquantile range and a thick box denoting position of the dominant (most frequently used TSS).

**Usage**

```r
exportToBed(object, what = c("CTSS", "tagClusters", "consensusClusters"),
qLow = NULL, qUp = NULL, colorByExpressionProfile = FALSE,
oneFile = TRUE)
```

## S4 method for signature 'CAGEr'

```r
exportToBed(object, what = c("CTSS", "tagClusters", "consensusClusters"),
qLow = NULL, qUp = NULL, colorByExpressionProfile = FALSE, oneFile = TRUE)
```

**Arguments**

- **object**
  - A CAGEr object.

- **what**
  - Which elements should be exported to BED track. *CTSS* to export individual CTSSs, *tagClusters* to export tag clusters or *consensusClusters* to export consensus clusters.

- **qLow, qUp**
  - Position of which "lower" (resp. "upper") quantile should be used as 5' (resp. 3') boundary of the filled block in gene-like representation of the cluster. Default value NULL uses start (resp. end) position of the cluster. Ignored when what = "CTSS".

- **colorByExpressionProfile**
  - Logical, should blocks be colored in the color of their corresponding expression class. Ignored when what = "tagClusters".

- **oneFile**
  - Logical, should all CAGE datasets be exported as individual tracks into the same BED file (TRUE) or into separate BED files (FALSE). Ignored when what = "CTSS", which by default produces only one track.

**Details**

The BED representations of *CTSSs*, *tag cluster* and *consensus clusters* can be directly visualised in the ZENBU or UCSC Genome Browsers.

When what = "CTSS", one BED file with single track of 1 bp blocks representing all detected CTSSs (in all CAGE samples) is created. CTSSs can be colored according to their expression class (provided the expression profiling of CTSSs was done by calling `getExpressionProfiles` function). Colors of expression classes match the colors in which they are shown in the plot returned by the `plotExpressionProfiles` function. For colorByExpressionProfile = FALSE, CTSSs included in the clusters are shown in black and CTSSs that were filtered out in gray.
When what = "tagClusters", one track per CAGE dataset is created, which can be exported to a single BED file (by setting oneFile = TRUE) or separate BED files (FALSE). If no quantile boundaries were provided (qLow and qUp are NULL), TCs are represented as simple blocks showing the full span of TC from the start to the end. Setting qLow and/or qUp parameters to a value of the desired quantile creates a gene-like representation with a line showing full span of the TC, filled block showing specified interquantile range and a thick 1 bp block denoting position of the dominant (most frequently used) TSS. All TCs in one track (one CAGE dataset) are shown in the same color.

When what = "consensusClusters" consensus clusters are exported to BED file. Since there is only one set of consensus clusters common to all CAGE datasets, only one track is created in case of a simple representation. This means that when qLow = NULL and qUp = NULL one track with blocks showing the full span of consensus cluster from the start to the end is created. However, the distribution of the CAGE signal within consensus cluster can be different in different CAGE samples, resulting in different positions of quantiles and dominant TSS. Thus, when qLow and/or qUp parameters are set to a value of the desired quantile, a separate track with a gene-like representation is created for every CAGE dataset. These tracks can be exported to a single BED file (by setting oneFile = TRUE) or separate BED files (by setting oneFile = FALSE). The gene-like representation is analogous to the one described above for the TCs. In all cases consensus clusters can be colored according to their expression class (provided the expression profiling of consensus clusters was done by calling getExpressionProfiles function). Colors of expression classes match the colors in which they are shown in the plot returned by the plotExpressionProfiles function. For colorByExpressionProfile = FALSE all consensus clusters are shown in black.

Value

Creates BED file(s) in the working directory.

expressionClasses

Extract labels of expression classes

Description

Retrieves labels of expression classes of either individual CTSSs or consensus clusters from a CAGEset object.

Usage

expressionClasses(object, what = c("CTSS", "consensusClusters"))

## S4 method for signature 'CAGEset'
expressionClasses(object, what = c("CTSS", "consensusClusters"))

## S4 method for signature 'CAGEexp'
expressionClasses(object, what = c("CTSS", "consensusClusters"))

Arguments

object  A CAGEset object.
what     Which level of expression clustering should be used. Can be either "CTSS" to extract labels of expression classes of individual CTSSs or "consensusClusters" to extract labels of expression classes of consensus clusters.

Value

Returns character vector of labels of expression classes. The number of labels matches the number of expression clusters returned by getExpressionProfiles function.

See Also

getExpressionProfiles plotExpressionProfiles extractExpressionClass

Examples

data <- expressionClasses(exampleCAGEset, what = "CTSS")
data
**extractExpressionClass**

*Extract elements of the specified expression class*

**Description**

Extracts CTSSs or consensus clusters belonging to a specified expression class.

**Usage**

```r
extractExpressionClass(object, what, which = "all")
```

## S4 method for signature 'CAGEexp'
```r
extractExpressionClass(object, what, which = "all")
```

## S4 method for signature 'CAGEset'
```r
extractExpressionClass(object, what, which = "all")
```

**Arguments**

- `object`: A `CAGEset` object.
- `what`: Which level of expression clustering should be used. Can be either "CTSS" to extract expression class of individual CTSSs or "consensusClusters" to extract expression class of consensus clusters.
- `which`: Which expression class should be extracted. It has to be one of the valid expression class labels (as returned by `expressionClasses` function), or "all" to extract members of all expression classes.

**Value**

Returns a `data.frame` of CTSSs (when `what = "CTSS"`) or consensus clusters (when `what = "consensusClusters"`) belonging to a specified expression class, with genomic coordinates and additional information. Last column contains the label of the corresponding expression class.

**Author(s)**

Vanja Haberle

**See Also**

`getExpressionProfiles, plotExpressionProfiles, expressionClasses`.

**Examples**

```r
CTSSexprClasses <- extractExpressionClass(exampleCAGEset, what = "CTSS", which = "all")

```
**FANTOM5mouseSamples**

**List of FANTOM5 human CAGE samples**

**Description**

This is a data.frame object that contains information about all human primary cell, cell line and tissue CAGE datasets (988 datasets) produced by FANTOM5 consortium, which are available for import with CAGEr. The list contains all samples published in the main FANTOM5 publication (Forrest et al. Nature 2014) as presented in the Supplementary Table 1. The columns provide the following information:

- **sample**: name/label of individual sample, which can be used as sample argument in the `importPublicData` function to retrieve specified sample.
- **type**: type of the sample, either "cell line", "primary cell" or "tissue".
- **description**: description of individual sample as provided by the FANTOM5 consortium.
- **library_id**: unique ID of the CAGE library as provided by the FANTOM5 consortium.
- **data_url**: URL to gzip-ed TSS file at online FANTOM5 data resource, which is used by `importPublicData` to fetch given sample.

**Usage**

```r
data(FANTOM5humanSamples)
```

**Format**

A data.frame object

---

**FANTOM5mouseSamples**

**List of FANTOM5 mouse CAGE samples**

**Description**

This is a data.frame object that contains information about all mouse primary cell, cell line and tissue CAGE datasets (395) produced by FANTOM5 consortium, which are available for import with CAGEr. The list contains all samples published in the main FANTOM5 publication (Forrest et al. Nature 2014) as presented in the Supplementary Table 1. The columns provide the following information:

- **sample**: name/label of individual sample, which can be used as sample argument in the `importPublicData` function to retrieve specified sample.
- **type**: type of the sample, either "cell line", "primary cell" or "tissue".
- **description**: description of individual sample as provided by the FANTOM5 consortium.
- **library_id**: unique ID of the CAGE library as provided by the FANTOM5 consortium.
- **data_url**: URL to gzip-ed TSS file at online FANTOM5 data resource, which is used by `importPublicData` to fetch given sample.

**Usage**

```r
data(FANTOM5humanSamples)
```

**Format**

A data.frame object
**Description**

Creates a DESeqDataSet using the gene expression data in the experiment slot `geneExpMatrix` and the sample metadata of the `CAGEexp` object. The formula must be built using factors already present in the sample metadata.

**Usage**

```
GeneExpDESeq2(object, design)
```

### S4 method for signature 'CAGEset'

```
GeneExpDESeq2(object, design)
```

### S4 method for signature 'CAGEexp'

```
GeneExpDESeq2(object, design)
```

**Arguments**

- `object` A `CAGEexp` object.
- `design` A formula for the DESeq2 analysis.

**Author(s)**

Charles Plessy

Retrieves the `SummarizedExperiment` containing gene expression levels.

**Description**

Get or set a `SummarizedExperiment` using the gene expression data in the experiment slot `geneExpMatrix` and the sample metadata of the `CAGEexp` object.

**Usage**

```r
GeneExpSE(object)
```

**Arguments**

- `object` A `CAGEexp` object.

**Author(s)**

Charles Plessy

**See Also**

Other CAGEr accessor methods: `CTSSclusteringMethod`, `CTSScoordinates`, `CTSScumulativesTagClusters`, `CTSSnormalizedTpm`, `CTSStagCountTable`, `CTSStagCount`, `GeneExpDESeq2`, `consensusClustersGR`, `genomeName`, `inputFilesType`, `inputFiles`, `librarySizes`, `sampleLabels`, `seqNameTotalsSE`, `tagClusters`

**Examples**

```r
GeneExpSE(exampleCAGEexp)
```

---

**genomeName**

Extracting genome name from CAGEr objects

**Description**

Extracts the name of a referent genome from a `CAGEset` and `CAGEexp` objects.
Usage

```r
genomeName(object)
```

## S4 method for signature 'CAGEset'

```r
genomeName(object)
```

## S4 method for signature 'CAGEexp'

```r
genomeName(object)
```

## S4 method for signature 'CTSS'

```r
genomeName(object)
```

```r
genomeName(object) <- value
```

## S4 replacement method for signature 'CAGEset'

```r
genomeName(object) <- value
```

## S4 replacement method for signature 'CAGEexp'

```r
genomeName(object) <- value
```

## S4 replacement method for signature 'CTSS'

```r
genomeName(object) <- value
```

Arguments

- **object**: A CAGEset or CAGEexp object.
- **value**: The name of a BSgenome package.

Details

*CAGEexp* objects constructed with NULL in place of the genome name can not run some commands that need access to genomic data, such as BigWig export or G-correction.

Value

Returns a name of a BSgenome package used as a referent genome.

Examples

```r
genomeName(exampleCAGEset)
```
getCTSS

Reading CAGE data from input file(s) and detecting TSSs

Description

Reads input CAGE datasets into CAGEr object, constructs CAGE transcriptions start sites (CTSSs) and counts number of CAGE tags supporting every CTSS in each input experiment. See inputFileType for details on the supported input formats. Preprocessing and quality filtering of input CAGE tags, as well as correction of CAGE-specific 'G' nucleotide addition bias can be also performed before constructing TSSs.

Usage

getCTSS(object, sequencingQualityThreshold = 10, mappingQualityThreshold = 20, removeFirstG = TRUE, correctSystematicG = TRUE, useMulticore = FALSE, nrCores = NULL)

## S4 method for signature 'CAGEset'
ggetCTSS(object, sequencingQualityThreshold = 10, mappingQualityThreshold = 20, removeFirstG = TRUE, correctSystematicG = TRUE, useMulticore = FALSE, nrCores = NULL)

## S4 method for signature 'CAGEexp'
ggetCTSS(object, sequencingQualityThreshold = 10, mappingQualityThreshold = 20, removeFirstG = TRUE, correctSystematicG = TRUE, useMulticore = FALSE, nrCores = NULL)

Arguments

object A CAGEset or a CAGEexp object.
sequencingQualityThreshold Only CAGE tags with average sequencing quality >= sequencingQualityThreshold and mapping quality >= mappingQualityThreshold are kept. Used only if inputFileType(object) == "bam" or inputFileType(object) == "bamPairedEnd", i.e when input files are BAM files of aligned sequenced CAGE tags, otherwise ignored. If there are no sequencing quality values in the BAM file (e.g. HeliScope single molecule sequencer does not return sequencing qualities) all reads will by default have this value set to -1. Since the default value of sequencingQualityThreshold is 10, all the reads will consequently be discarded. To avoid this behaviour and keep all sequenced reads set sequencingQualityThreshold to -1 when processing data without sequencing qualities. If there is no information on mapping quality in the BAM file (e.g. software used to align CAGE tags to the referent genome does not provide mapping quality) the mappingQualityThreshold parameter is ignored. In case of paired-end sequencing BAM file (i.e. inputFileType(object) == "bamPairedEnd") only the first mate of the properly paired reads (i.e. the five prime end read) will be read and subject to specified thresholds.
mappingQualityThreshold See sequencingQualityThreshold.
removeFirstG Logical, should the first nucleotide of the CAGE tag be removed in case it is a G and it does not map to the referent genome (i.e. it is a mismatch).
getCTSS

Used only if `inputFileType(object) == "bam"` or `inputFileType(object) == "bamPairedEnd"`, i.e. when input files are BAM files of aligned sequenced CAGE tags, otherwise ignored. See Details.

`correctSystematicG` Logical, should the systematic correction of the first G nucleotide be performed for the positions where there is a G in the CAGE tag and G in the genome. This step is performed in addition to removing the first G of the CAGE tags when it is a mismatch, i.e. this option can only be used when `removeFirstG = TRUE`, otherwise it is ignored. The frequency of adding a G to CAGE tags is estimated from mismatch cases and used to systematically correct the G addition for positions with G in the genome. Used only if `inputFileType(object) == "bam"` or `inputFileType(object) == "bamPairedEnd"`, i.e when input files are BAM files of aligned sequenced CAGE tags, otherwise ignored. See Details.

`useMulticore` Logical, should multicore be used. `useMulticore = TRUE` has no effect on non-Unix-like platforms.

`nrCores` Number of cores to use when `useMulticore = TRUE` (set to `NULL` to use all detected cores).

**Details**

In the CAGE experimental protocol an additional G nucleotide is often attached to the 5' end of the tag by the template-free activity of the reverse transcriptase used to prepare cDNA (Harbers and Carninci, Nature Methods 2005). In cases where there is a G at the 5' end of the CAGE tag that does not map to the corresponding genome sequence, it can confidently be considered spurious and should be removed from the tag to avoid misannotating actual TSS. Thus, setting `removeFirstG = TRUE` is highly recommended.

However, when there is a G both at the beginning of the CAGE tag and in the genome, it is not clear whether the original CAGE tag really starts at this position or the G nucleotide was added later in the experimental protocol. To systematically correct CAGE tags mapping at such positions, a general frequency of adding a G to CAGE tags can be calculated from mismatch cases and applied to estimate the number of CAGE tags that have G added and should actually start at the next nucleotide/position. The option `correctSystematicG` is an implementation of the correction algorithm described in Carninci *et al.*, Nature Genetics 2006, Supplementary Information section 3-e.

**Value**

For `CAGEset` objects, the slots `librarySizes`, `CTSScoordinates` and `tagCountMatrix` will be occupied by the information on CTSSs created from input CAGE files. For `CAGEexp` objects, the `tagCountMatrix` experiment will be occupied by a SummarizedExperiment containing the expression data as a DataFrame of Rle integers, and the CTSS coordinates as a GRanges object. In both cases the expression data can be retrieved with `CTSStagCount` functions. In addition, the library sizes are calculated and stored in the object.

pathsToInputFiles <- system.file("extdata", c("Zf.unfertilized.egg.chr17.ctss", "Zf.30p.dome.chr17.ctss", "Zf.prim6.rep1.chr17.ctss"), package="CAGEr")

labels <- paste("sample", seq(1,3,1), sep = "")

myCAGEset <- new("CAGEset", genomeName = "BSgenome.Drerio.UCSC.danRer7", inputFiles = pathsToInputFiles, inputFilesType = "ctss", sampleLabels = labels)

getCTSS(myCAGEset)
```

---

### getExpressionProfiles

**CAGE data based expression clustering**

**Description**

Clusters CAGE expression across multiple experiments, both at level of individual TSSs or entire clusters of TSSs.

**Usage**

```r
getExpressionProfiles(object, what, tpmThreshold = 5, nrPassThreshold = 1, method = "som", xDim = 5, yDim = 5)
```

**Arguments**

- **object**: A `CAGEset` object
- **what**: At which level should the expression clustering be done. Can be either "CTSS" to perform clustering of individual CTSSs or "consensusClusters" to perform clustering of consensus clusters. See Details.
- **tpmThreshold**, **nrPassThreshold**: Only CTSSs or consensus clusters (depending on `what` parameter) with normalized CAGE signal $\geq$ `tpmThreshold` in $\geq$ `nrPassThreshold` experiments will be included in expression clustering.
getExpressionProfiles

Method to be used for expression clustering. Can be either "som" to use the self-organizing map (SOM) algorithm (Toronen et al., FEBS Letters 1999) implemented in the `som` function from `som` package, or "kmeans" to use the K-means algorithm implemented in the `kmeans` function from `stats` package.

`xDim`, `yDim`
When `method = "kmeans"`, `xDim` specifies number of clusters that will be returned by K-means algorithm and `yDim` is ignored. When `method = "som"`, `xDim` specifies the the first and `yDim` the second dimension of the self-organizing map, which results in total `xDim * yDim` clusters returned by SOM.

Details

Expression clustering can be done at level of individual CTSSs, in which case the feature vector used as input for clustering algorithm contains log-transformed and scaled (divided by standard deviation) normalized CAGE signal at individual TSS across multiple experiments. Only TSSs with normalized CAGE signal >= `tpmThreshold` in at least `nrPassThreshold` CAGE experiments are used for expression clustering. However, CTSSs along the genome can be spatially clustered into tag clusters for each experiment separately using the `clusterCTSS` function, and then aggregated across experiments into consensus clusters using `aggregateTagClusters` function. Once the consensus clusters have been created, expression clustering at the level of these wider genomic regions (representing entire promoters rather than individual TSSs) can be performed. In that case the feature vector used as input for clustering algorithm contains normalized CAGE signal within entire consensus cluster across multiple experiments, and threshold values in `tpmThreshold` and `nrPassThreshold` are applied to entire consensus clusters.

Value

If `what = "CTSS"` the slots `CTSSexpressionClusteringMethod` and `CTSSexpressionClasses` will be occupied, and if `what = "consensusClusters"` the slots `consensusClustersExpressionClusteringMethod` and `consensusClustersExpressionClasses` of the provided `CAGEset` object will be occupied with the results of expression clustering. Labels of expression classes (clusters) can be retrieved using `expressionClasses` function, and elements belonging to a specific expression class can be selected using `extractExpressionClass` function.

```r
getExpressionProfiles(exampleCAGEset, what = "CTSS", tpmThreshold = 50, nrPassThreshold = 1, method = "som", xDim = 3, yDim = 3)
```
getShiftingPromoters

Select consensus clusters with shifting score above threshold

Description

Extracts consensus clusters with shifting score and/or FDR (adjusted P-value from Kolmogorov-Smirnov test) above specified threshold. Returns their genomic coordinates, total CAGE signal and the position of dominant TSS in the two compared groups of CAGE samples, along with the value of the shifting score, P-value and FDR. Scores and P-values/FDR have to be calculated beforehand by calling scoreShift function.

Usage

getShiftingPromoters(object, tpmThreshold = 0, scoreThreshold = -Inf, fdrThreshold = 1)

## S4 method for signature 'CAGEset'
getShiftingPromoters(object, tpmThreshold = 0, scoreThreshold = -Inf, fdrThreshold = 1)

Arguments

- **object**: A CAGEset object.
- **tpmThreshold**: Consensus clusters with total CAGE signal >= tpmThreshold in each of the compared groups will be returned.
- **scoreThreshold**: Consensus clusters with shifting score >= scoreThreshold will be returned. The default value -Inf returns all consensus clusters (for which score could be calculated, i.e. the ones that have at least one tag in each of the compared samples).
- **fdrThreshold**: Consensus clusters with adjusted P-value (FDR) from Kolmogorov-Smirnov test >= fdrThreshold will be returned. The default value 1 returns all consensus clusters (for which K-S test could be performed, i.e. the ones that have at least one tag in each of the compared samples).

Value

Returns a data.frame of shifting promoters with genomic coordinates and positions of dominant TSS and CAGE signal in the two compared (groups of) samples, along with shifting score and adjusted P-value (FDR).

, scoreThreshold = 0.4, fdrThreshold = 0.01))
```

---

**Description**

Rarefy data at multiple sample sizes using the vegan package and return a ‘hanabi’ object that can be passed to plot functions.

The computation can be long, so the steps of rarefaction and plotting are kept separate.

**Usage**

```r
hanabi(x, n = 20, step = 0.75, from = NULL, useMulticore = FALSE,
nrCores = NULL)
```

```r
## S4 method for signature 'Rle'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'numeric'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'integer'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'GRanges'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'List'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'list'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```

```r
## S4 method for signature 'matrix'
hanabi(x, n = 20, step = 0.75, from = NULL,
useMulticore = FALSE, nrCores = NULL)
```
Arguments

- **x**: An object contained expression counts on which richness scores can be calculated. For example, an expression table in `DataFrame` or `data.frame` format where columns are samples and rows are features such as genes, TSS, etc., or a vector of counts (tag counts, molecule counts, ...), or `GRanges` or `GRangesList` objects, etc.

- **n**: The maximum number of rarefactions per sample.

- **step**: Subsample sizes are calculated by taking the largest sample and multiplying it by the step “n” times.

- **from**: Add one sample size (typically "0") in order to extend the plot on the left-hand side.

- **useMulticore**: Logical, should multicore be used. `useMulticore = TRUE` has no effect on non-Unix-like platforms. At the moment, it also has only effects on lists and list-derived classes (data frames but not matrices).

- **nrCores**: Number of cores to use when `useMulticore = TRUE` (set to `NULL` to use all detected cores).

Details

This function does not take directly CAGEr objects as input, because hanabi plots can be made from CTSS, clustered or gene-level data, therefore it is not possible to guess which one to use.

Value

A list-based object of class "hanabi".

h <- hanabi(CTSStagCountDF(exampleCAGEexp))
h
plot(h)
hanabi(CTSStagCountGR(exampleCAGEexp, 2))
```

Description

TBD

Details

TBD
Description

Plot feature discovery curves

Usage

hanabiPlot(x, group, col = NULL, legend.pos = "topleft", pch = 1, ...)

Arguments

x A hanabi object.
group A character vector or a factor grouping the samples.
col A character vector colors (at most one per group).
legend.pos Position of the legend, passed to the legend function.
pch Plot character at the tip of the lines and in the legend.
... Further arguments to be passed to the plot.hanabi function.

Details

Plots the number of features (genes, transcripts, ...) detected for a given number of counts (reads, unique molecules, ...). Each library is sub-sampled by rarefaction at various sample sizes, picked to provide enough points so that the curves look smooth. The final point is plotted as an open circle, hence the name "hanabi", which means fireworks in Japanese.

The rarefactions take time to do, so this step is done by a separate function, so that the result is easily cached.

CAGEr::import.CTSS(system.file("extdata", "Zf.high.chr17.ctss", package = "CAGEr"))

importPublicData

Importing publicly available CAGE data from various resources

Description

Imports CAGE data from different sources into a CAGEset object. After the CAGEset object has been created the data can be further manipulated and visualized using other functions available in the CAGEr package and integrated with other analyses in R. Available resources include:
- FANTOM5 datasets (Forrest et al. Nature 2014) for numerous human and mouse samples (primary cells, cell lines and tissues), which are fetched directly from FANTOM5 online resource.
- ENCODE datasets (Djebali et al. Nature 2012) for numerous human cell lines from ENCODEprojectCAGE data package, which is available for download from http://promshift.genereg.net/CAGEr/.
- Zebrafish developmental timecourse datasets (Nepal et al. Genome Research 2013) from ZebrafishDevelopmentalCAGE data package, which is available for download from http://promshift.genereg.net/CAGEr/.

Usage

importPublicData(source, dataset, group, sample)

Arguments

source Character vector specifying one of the available resources for CAGE data. Can be one of the following:
"FANTOM5": for fetching and importing CAGE data for various human or mouse primary cells, cell lines and tissues from the online FANTOM5 resource (http://fantom.gsc.riken.jp/5/data/).
All data published in main FANTOM5 publication by Forrest et al. is available.
"FANTOM3and4": for importing CAGE data for various human or mouse tissues produced within FANTOM3 and FANTOM4 projects. Requires data package FANTOM3and4CAGE to be installed. This data package is available from Bioconductor.
"ENCODE": for importing CAGE data for human cell lines from ENCODE project published by Djebali et al.. Requires data package ENCODEprojectCAGE to be installed. This data package is available for download from http://promshift.genereg.net/CAGEr/.
"ZebrafishDevelopment": for importing CAGE data from developmental timecourse of zebrafish (Danio rerio) published by Nepal et al.. Requires data package ZebrafishDevelopmentalCAGE to be installed. This data package is available for download from http://promshift.genereg.net/CAGEr/.
See Details for further explanation of individual resources.
importPublicData

**dataset**
Character vector specifying one or more of the datasets available in the selected resource. For FANTOM it can be either "human" or "mouse", and only one of them can be specified at a time. For other resources please refer to the vignette of the corresponding data package for the list of available datasets. Multiple datasets mapped to the same genome can be specified to combine selected samples from each.

**group**
Character string specifying one or more groups within specified dataset(s), from which the samples should be selected. group argument is used only when importing TSSs from data packages and ignored when source="FANTOM5". For available groups in each dataset please refer to the vignette of the corresponding data package. Either only one group has to be specified (if all selected samples belong to the same group) or one group per sample (if samples belong to different groups). In the latter case, the number of elements in group must match the number of elements in sample.

**sample**
Character string specifying one or more CAGE samples. Check the corresponding data package for available samples within each group and their labels. For FANTOM5 resource, list of all human (~1000) and mouse (~) samples can be obtained in CAGEr by loading data(FANTOM5humanSamples) and data(FANTOM5mouseSamples), respectively. Use the names from the sample column to specify which samples should be imported.

**Details**
CAGE data from different sources is available for importing directly into CAGEset object for further manipulation with CAGEr.

FANTOM consortium provides single base-pair resolution TSS data for numerous human and mouse primary cells, cell lines and tissues produced within FANTOM5 project (Forrest et al. Nature 2014). These are directly fetched from their online resource at http://fantom.gsc.riken.jp/5/data and imported into a CAGEset object. To use this resource specify source="FANTOM5". The dataset argument can be either "human" or "mouse", but not both at the same time. The list of all human and mouse samples can be obtained by loading data(FANTOM5humanSamples) and data(FANTOM5mouseSamples). The sample column gives the names of individual samples that should be provided as sample argument. See example below.

TSS data from previous FANTOM3 and FANTOM4 projects (Carninci et al., Faulkner et al., Suzuki et al.) are also available through FANTOM3and4CAGE data package. This data package can be installed directly from Bioconductor. To use this resource install and load FANTOM3and4CAGE package and specify source="FANTOM3and4". The dataset argument can be a name of any of the datasets available in this package. Load data(FANTOM3humanSamples) or data(FANTOM3mouseSamples) for the list of available datasets with group and sample labels for specific human or mouse samples. These have to be provided as dataset, group and sample arguments to import selected samples. If all samples belong to the same group, only this one group can be provided, otherwise, for each sample a corresponding group has to be specified, i.e. the number of elements in group must match the number of elements in sample.

ENCODE consortium produced CAGE data for numerous human cell lines (Djebali et al. Nature 2012). We have used these data to derive single base-pair resolution TSSs and collected them into an R data package ENCODEprojectCAGE. This data package is available for download from http://promshift.genereg.net/CAGEr/. To use this resource install and load ENCODEprojectCAGE data package and specify source="ENCODE". The dataset argument can be a name of any of the datasets available in this package. Load data(ENCODHumanCellLinesSamples) for the list of available datasets with group and sample labels for specific samples. These have to be provided as dataset, group and sample arguments to import selected samples. Multiple datasets can be combined together, by specifying them as dataset argument. If all samples belong to the same dataset
and the same group, these dataset and group can be specified only once, otherwise, for each sample a corresponding dataset and group have to be specified, i.e. the number of elements in dataset and group must match the number of elements in sample. Precise TSSs are also available for zebrafish (Danio Rerio) from CAGE data published by Nepal et al. for 12 developmental stages. These have been collected into a data package ZebrafishDevelopmentalCAGE, which is available for download from http://promshift.genereg.net/CAGEr/. To use this resource install and load ZebrafishDevelopmentalCAGE data package and specify source="ZebrafishDevelopment". Load data(ZebrafishSamples) for the list of available datasets and group and sample labels, which have to be specified to import these data.

Value

A CAGEset object is returned. Slots librarySizes, CTSScoordinates and tagCountMatrix are occupied by the single base-pair resolution TSS data imported from the selected resource.

```

### importing FANTOM3/4 data from a data package

```R
library(FANTOM3and4CAGE)
```
# list of mouse datasets available in this package
data(FANTOMmouseSamples)
unique(FANTOMmouseSamples$dataset)
head(subset(FANTOMmouseSamples, dataset == "FANTOMtissueCAGEmouse"))
head(subset(FANTOMmouseSamples, dataset == "FANTOMtimecourseCAGEmouse"))

# import selected samples from two different mouse datasets
exampleCAGEset <- importPublicData(source="FANTOM3and4",
  dataset = c("FANTOMtissueCAGEmouse", "FANTOMtimecourseCAGEmouse"),
  group = c("brain", "adipogenic_induction"),
  sample = c("CCL-131_Neuro-2a_treatment_for_6hr_with_MPP+", "DFAT-D1_preadipocytes_2days"))

exampleCAGEset

---

**inputFiles**

Extraction paths to input files from CAGEr objects

**Description**

Extracts the paths to CAGE data input files from CAGEset and CAGEexp objects.

**Usage**

inputFiles(object)

### S4 method for signature 'CAGEset'
inputFiles(object)

### S4 method for signature 'CAGEexp'
inputFiles(object)

inputFiles(object) <- value

### S4 replacement method for signature 'CAGEset'
inputFiles(object) <- value

### S4 replacement method for signature 'CAGEexp'
inputFiles(object) <- value

**Arguments**

- **object**: A CAGEset or CAGEexp object.
- **value**: A character vector with one file path per sample.

**Value**

Returns a character vector of paths to CAGE data input files.

**Author(s)**

inputFiles(exampleCAGEset)
```

---

inputFilesType | Input file formats for CAGEr objects

Description

Get or set the information on the type of CAGE data input files from `CAGEset` and `CAGEexp` objects.

Usage

```r
inputFilesType(object)
## S4 method for signature 'CAGEset'
inputFilesType(object)
## S4 method for signature 'CAGEexp'
inputFilesType(object)

inputFilesType(object) <- value
## S4 replacement method for signature 'CAGEset'
inputFilesType(object) <- value
## S4 replacement method for signature 'CAGEexp'
inputFilesType(object) <- value
```

Arguments

- `object` A CAGEset or CAGEexp object.
- `value` A character vector with one file type per sample.

Details

The following input file types are supported:

- `bed`: A BED file where each line counts for one molecule.
- `bedScore`: A BED file where the score indicates a number of counts for a given alignment
- `CAGEscanMolecule`: Experimental. For the CAGEscan 3.0 pipeline.
librarySizes

- ctss: A tabulation-delimited file describing CAGE Transcription Start Sites (CTSS) with four columns indicating chromosome, 1-based coordinate, strand and score respectively.
- CTSStable
- FANTOM5
- ENCODE
- FANTOM3and4
- ZebrafishDevelopment

Value

Returns the type of the file format of CAGE data input files, e.g. "bam" or "ctss". In the case of CAGEexp objects, the return value is character vector with one member per sample.

librarySizes

*Extracting library sizes from CAGEr objects*

Description

Extracts the library sizes (total number of CAGE tags) for all CAGE datasets from CAGEset and CAGEexp objects.

Usage

librarySizes(object)

## S4 method for signature 'CAGEset'
librarySizes(object)

## S4 method for signature 'CAGEexp'
librarySizes(object)
loadFileIntoGPos

Arguments

object A CAGEset or CAGEexp object.

Details

Library sizes are calculated when loading data with the getCTSS function and stored in the librarySizes slot of CAGEset objects, or in the librarySizes column of the colData of CAGEexp objects.

Value

Returns an integer vector of total number of CAGE tags (library size) for all CAGE datasets in the CAGEr object.

mapStats Process mapping statistics

Description

Using a data frame containing mapping statistics in counts, transform the data in percentages that can be used for stacked barplots.

Usage

mapStats(libs, scope, group = "default", facet = NULL, normalise = TRUE)

Arguments

libs A data frame with containing columns required by the scope chosen.
scope The name of a “scope”, that defines which data is plotted and how it is normalised, or a function that implements a custom scope. See mapStatsScopes() for details on each scope.
group A vector of factors defining groups in the data. By default, the “group” column of the “libs” table.
facet A vector of factors defining facets in the data (in the sense of ggplot2’s facet_wrap function).
normalise Whether to normalise or not. Default: TRUE.

details

See the plotAnnot vignette and the mapStatsScopes() help page for details on what the scopes are.

Value

Returns a data frame with mean and standard deviation of normalised mapping statistics, plus absolute positions for the error bars. The first column, group, is a vector of factors sorted with the gtools::mixedorder() function. The facet column, if any, is always called facet.

Examples

library(SummarizedExperiment)
CAGEr:::mapStats(as.data.frame(colData(exampleCAGEexp)), "counts", sampleLabels(exampleCAGEexp))
CAGEr:::mapStats(as.data.frame(colData(exampleCAGEexp)), "counts", c("A", "A", "B", "B", "C"))

Description

Functions implementing the scope parameter of the mapStats function.

Usage

msScope_counts(libs)
msScope_mapped(libs)
msScope_qc(libs)
msScope_steps(libs)
msScope_all(libs)
msScope_annotation(libs)

Arguments

libs A data frame containing metadata describing samples in sequence libraries.
mergeCAGEsets

Details
The counts scope reports the number of molecules aligning in promoter, exon, intron and otherwise intergenic regions.
The mapped scope reports the number of molecules aligning in promoter, exon, intron and otherwise intergenic, plus the number of PCR duplicates (mapped tags minus molecule counts), plus the number of non-properly paired mapped tags.
The qc scope reports the number of tags removed as tag dust, rRNA, spikes, plus the unmapped tags, plus the number of non-properly paired mapped tags, plus the number of PCR duplicates (mapped tags minus molecule counts), plus the number of unique molecule counts.
The steps scope reports the number of tags removed by cleaning, mapping, and deduplication, plus the number of unique molecule counts.
The legacy all scope reports the number of tags in promoters, exons, introns, or mapped elsewhere, or removed because they match rRNA or are likely primer artefacts, normalised by the total number of extracted tags.
The legacy annotation scope reports the number of tags in promoters, exons, introns, or mapped elsewhere, or removed because they match rRNA or are likely primer artefacts, normalised by the total number of mapped tags.

Value
Returns a list with three elements: lib contains a modified version of the input data frame where columns have been reorganised as needed, cols contains the names of the columns to use for plotting and provides the order of the stacked bars of the plotAnnot function, total indicates the total counts used for normalising the data.

mergeCAGEsets

Merge two CAGEr objects into one

Description
Merges two CAGEr objects into one by combining the CTSS genomic coordinates and raw tag counts. The resulting object will contain a union of TSS positions present in the two input objects and raw tag counts for those TSSs in all samples from both input objects.

Usage
mergeCAGEsets(cs1, cs2)

## S4 method for signature 'CAGEset,CAGEset'
mergeCAGEsets(cs1, cs2)

## S4 method for signature 'CAGEexp,CAGEexp'
mergeCAGEsets(cs1, cs2)

Arguments

  cs1       A CAGEr object
  cs2       A CAGEr object
mergeCAGEsets

Value

Note that merging discards all other information present in the two CAGEr objects, that is, the merged object will not contain any normalised tag counts, CTSS clusters, quantile positions, etc., so these have to be calculated again by calling the appropriate functions on the merged object. Also, it is only possible to merge two objects that contain TSS information for the same reference genome and do not share any sample names.

Returns a CAGEset or CAGEexp object, which contains a union of TSS positions present in the two input objects and raw tag counts for those TSSs in all samples from both input objects.

library(BSgenome.Drerio.UCSC.danRer7)

pathsToInputFiles <- system.file("extdata", c("Zf.unfertilized.egg.chr17.ctss", "Zf.30p.dome.chr17.ctss", "Zf.prim6.rep1.chr17.ctss"), package="CAGEr")

myCAGEset1 <- new("CAGEset", genomeName = "BSgenome.Drerio.UCSC.danRer7", inputFiles = pathsToInputFiles[1:2], inputFilesType = "ctss", sampleLabels = c("sample1", "sample2"))
getCTSS(myCAGEset1)

c1 <- CAGEexp(genomeName = "BSgenome.Drerio.UCSC.danRer7", inputFiles = pathsToInputFiles[1:2], inputFilesType = "ctss", sampleLabels = c("sample1", "sample2"))
getCTSS(c1)

myCAGEset2 <- new("CAGEset", genomeName = "BSgenome.Drerio.UCSC.danRer7", inputFiles = pathsToInputFiles[3], inputFilesType = "ctss", sampleLabels = "sample3")

c2 <- CAGEexp(genomeName = "BSgenome.Drerio.UCSC.danRer7", inputFiles = pathsToInputFiles[3], inputFilesType = "ctss", sampleLabels = "sample3")

c1 <- mergeCAGEsets(c1)

c2 <- mergeCAGEsets(c2)

c <- mergeCAGEsets(c1, c2)
mergeSamples

**Merge CAGE samples**

**Description**
Merges individual CAGE samples (datasets, experiments) within the CAGEr object into specified groups.

**Usage**
```r
mergeSamples(object, mergeIndex, mergedSampleLabels)
```

```r
## S4 method for signature 'CAGEset,numeric'
mergeSamples(object, mergeIndex, 
mergedSampleLabels)
```

```r
## S4 method for signature 'CAGEexp,ANY'
mergeSamples(object, mergeIndex, 
mergedSampleLabels)
```

**Arguments**
- `object` A CAGEr object.
- `mergeIndex` Integer vector specifying which experiments should be merged. (one value per sample, see Details).
- `mergedSampleLabels` Labels for the merged datasets (same length as the number of unique values in `mergeIndex`)

**Details**
The samples within the CAGEr object are merged by adding the raw tag counts of individual CTSS that belong to the same group. After merging, all other slots in the CAGEr object will be reset and any previous data for individual experiments will be removed.

`mergeIndex` controls which samples will be merged. It is an integer vector that assigns a group identifier to each sample, in the same order as they are returned by `sampleLabels(object)`. For example, if there are 8 CAGE samples in the CAGEr object and `mergeIndex = c(1,1,2,2,3,2,4,4)`, this will merge a) samples 1 and 2, b) samples 3, 4 and 6, c) samples 7 and 8, and d) it will leave sample 5 as it is, resulting in 4 final merged datasets.

Labels provided in `mergedSampleLabels` will be assigned to merged datasets in the ascending order of `mergeIndex` values, *i.e.* first label will be assigned to a dataset created by merging datasets labeled with lowest `mergeIndex` value (in this case 1), etc.

**Value**
The slots `sampleLabels`, `librarySizes` and `tagCountMatrix` of the provided CAGEr object will be updated with the information on merged CAGE datasets and will replace the previous information on individual CAGE datasets. All further slots with downstream information will be reset.
Author(s)

Vanja Haberle

Examples

```r
mergeSamples(exampleCAGEset,
    mergeIndex = c(1,1,2),
    mergedSampleLabels = c("mergedSample1", "mergedSample2"))

exampleCAGEset

mergeSamples(exampleCAGEexp,
    mergeIndex = c(3,2,4,4,1),
    mergedSampleLabels = c("zf_unfertilized", "zf_high", "zf_30p_dome", "zf_prim6"))

exampleCAGEexp
```

Description

Calculates CTSS positions from a GenomicRanges object where each element represents a single molecule.

Usage

```r
moleculesGR2CTSS(gr)
```

Arguments

- `gr` A GRanges object.

Value

Returns a GRanges object.

See Also

Other loadFileIntoGPos: bam2CTSS, import.CTSS, import.bam.ctss, import.bam, import.bedCTSS, import.bedScore, import.bedmolecule, loadFileIntoGPos

Examples

gr <- GenomicRanges::GRanges("chr1", IRanges::IRanges(1, 10), c("+", "+", "-", "+"))
CAGEr::moleculesGR2CTSS(gr)
```
normalizeTagCount

normalizing raw CAGE tag count

Description

Normalizes raw CAGE tag count per CTSS in all experiments to a same referent distribution. A simple tag per million normalization or normalization to a referent power-law distribution (Balwierz et al., Genome Biology 2009) can be specified.

Usage

```r
normalizeTagCount(object, method = c("powerLaw", "simpleTpm", "none"),
                  fitInRange = c(10, 1000), alpha = 1.25, T = 10^6)
```

## S4 method for signature 'CAGEset'
```r
normalizeTagCount(object, method = c("powerLaw", "simpleTpm", "none"), fitInRange = c(10, 1000), alpha = 1.25, T = 10^6)
```

## S4 method for signature 'CAGEexp'
```r
normalizeTagCount(object, method = c("powerLaw", "simpleTpm", "none"), fitInRange = c(10, 1000), alpha = 1.25, T = 10^6)
```

Arguments

- `object`: A `CAGEset` object
- `method`: Method to be used for normalization. Can be either "simpleTpm" to convert tag counts to tags per million or "powerLaw" to normalize to a referent power-law distribution, or "none" to keep using the raw tag counts in downstream analyses.
- `fitInRange`: An integer vector with two values specifying a range of tag count values to be used for fitting a power-law distribution to reverse cumulatives. Used only when `method = "powerLaw"`, otherwise ignored. See Details.
- `alpha`: \(-1 \times \alpha\) will be the slope of the referent power-law distribution in the log-log representation. Used only when `method = "powerLaw"`, otherwise ignored. See Details.
- `T`: Total number of CAGE tags in the referent power-law distribution. Setting \(T = 10^6\) results in normalized values that correspond to tags per million in the referent distribution. Used only when `method = "powerLaw"`, otherwise ignored. See Details.

Details

It has been shown that many CAGE datasets follow a power-law distribution (Balwierz et al., Genome Biology 2009). Plotting the number of CAGE tags (X-axis) against the number of TSSs that are supported by \(\geq\) of that number of tags (Y-axis) results in a distribution that can be approximated by a power-law. On a log-log scale this theoretical referent distribution can be described by a monotonically decreasing linear function \(y = -1 \times \alpha x + \beta\), which is fully determined by the slope \(\alpha\) and total number of tags \(T\) (which together with \(\alpha\) determines the value of \(\beta\)). Thus, by specifying parameters \(\alpha\) and \(T\) a desired referent power-law distribution.
can be selected. However, real CAGE datasets deviate from the power-law in the areas of very low and very high number of tags, so it is advisable to discard these areas before fitting a power-law distribution. The `fitInRange` parameter allows to specify a range of values (lower and upper limit of the number of CAGE tags) that will be used to fit a power-law. Plotting reverse cumulatives using `plotReverseCumulatives` function can help in choosing the best range of values. After fitting a power-law distribution to each CAGE dataset individually, all datasets are normalized to a referent distribution specified by `alpha` and `T`. When \( T = 10^6 \), normalized values are expressed as tags per million (tpm).

### Value

The slot `normalizedTpmMatrix` of the provided `CAGEset` object will be occupied by normalized CAGE signal values per CTSS across all experiments, or with the raw tag counts (in case `method = "none"`).

**Parse a string describing a block in a CAGEscan molecule, as output by the "CAGEscan 3.0" pipeline.**

### Usage

```r
parseCAGEscanBlocksToGrangeTSS(blocks)
```
### plot.hanabi

**Arguments**

blocks

A character string representing a block in a CAGEscan molecule.

**Value**

A GRanges object representing a TSS.

In CAGEscan molecules, blocks are separated by ‘|’, ‘,’ or ‘;’ for gap of coverage, splice junction (confident) and splice junction (maybe) respectively. Strand is "+" if first coordinate is lower than the second one, and "-" otherwise.

**See Also**

import.CAGEscanMolecule

```

---

### plot.hanabi

**Plotting Hanabi objects**

**Description**

S3 method to plot hanabi objects. Used by the `hanabiPlot` function.

**Usage**

```r
## S3 method for class 'hanabi'
plot(x, alpha = 0.5, col = "black",
     xlab = "Total counts", ylab = "Unique features",
     main = "Hanabi plot", pch = 1, ...)
## S3 method for class 'hanabi'
points(x, ...)
## S3 method for class 'hanabi'
lines(x, ...)
```

**Arguments**

- `x` The hanabi object to plot.
- `alpha` The alpha transparency of the plot lines.
- `col` A vector indicating a color per sample (or a vector that can be recycled that way).
- `xlab` Horizontal axis label.
plotAnnot

<table>
<thead>
<tr>
<th>ylab</th>
<th>Vertical axis label.</th>
</tr>
</thead>
<tbody>
<tr>
<td>main</td>
<td>Plot title.</td>
</tr>
<tr>
<td>pch</td>
<td>Plot character at the tip of the lines.</td>
</tr>
<tr>

plotAnnot | *Plot annotation statistics*

Description

Plot mapping statistics of an object containing mapping statistics in counts as percentages in stacked barplots.

Usage

```r
plotAnnot(x, scope, title, group = "default", facet = NULL, normalise = TRUE)
```

## S4 method for signature 'data.frame'
plotAnnot(x, scope, title, group = "default", facet = NULL, normalise = TRUE)

## S4 method for signature 'DataFrame'
plotAnnot(x, scope, title, group = "default", facet = NULL, normalise = TRUE)

## S4 method for signature 'CAGEexp'
plotAnnot(x, scope, title, group = "default", facet = NULL, normalise = TRUE)

Arguments

- **x**: An object from which can be extracted a table with columns named `promoter`, `exon`, `intron`, `mapped`, `extracted`, `rdna`, and `tagdust`, that will be passed to the `mapStats` function.

- **scope**: The name of a “scope”, that defines which data is plotted and how it is normalised, or a function implementing that scope. See `mapStatsScopes()` for details on each scope.

- **title**: The title of the plot.

- **group**: A factor to group the samples, or the name of a `colData` column of a `CAGEexp` object, or a formula giving the names of columns to be pasted together.

- **facet**: A factor or the name of a `colData` column of a `CAGEexp` object, to facet the samples in the sense of `ggplot2`'s `facet_wrap` function.

- **normalise**: Whether to normalise or not. Default: TRUE.
plotCorrelation

Details

Value

Returns invisibly a ggplot2 object of class c("gg", "ggplot").

Author(s)

Charles Plessy

mapStats() for a list of scopes.

Other CAGEr annotation functions: annotateCTSS, ranges2annot, ranges2genes, ranges2names

Other CAGEr plot functions: hanabiPlot, plotCorrelation, plotExpressionProfiles, plotInterquantileWidth, plotReverseCumulatives

Examples

```r
p <- plotAnnot(exampleCAGEexp, 'counts', 'Here is the title')
print(p)
p + ggplot2::theme_bw()
ggplot2::theme_set(ggplot2::theme_bw()); p
plotAnnot(exampleCAGEexp, 'counts', 'Same, non-normalised', normalise = FALSE)
exampCAGEexp$myGroups <- factor(c("A", "A", "B", "B", "C"))
plotAnnot(exampleCAGEexp, 'counts', group = "myGroups")
plotAnnot(exampleCAGEexp, 'counts', group = ~myGroups)
plotAnnot(exampleCAGEexp, 'counts', group = ~sampleLabels + myGroups)
plotAnnot(exampleCAGEexp, CAGEr::msScope_counts, group = "myGroups")
```

plotCorrelation  
Pairwise scatter plots and correlations of CAGE signal

Description

Calculates the pairwise correlation between samples and creates a plot matrix showing the correlation coefficients in the upper triangle, the sample names in the diagonal, and the scatter plots in the lower triangle.

Usage

```r
plotCorrelation(object, what = c("CTSS", "consensusClusters"),
values = c("raw", "normalized"), samples = "all",
method = "pearson", tagCountThreshold = 1,
applyThresholdBoth = FALSE, plotSize = 800)
```

## S4 method for signature 'CAGEr'
plotCorrelation(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, plotSize = 800)

plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'CAGEset'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'CAGEexp'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'SummarizedExperiment'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'DataFrame'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'data.frame'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

## S4 method for signature 'matrix'
plotCorrelation2(object, what = c("CTSS", "consensusClusters"), values = c("raw", "normalized"), samples = "all", method = "pearson", tagCountThreshold = 1, applyThresholdBoth = FALSE, digits = 3)

Arguments

object A CAGEr object or (only for plotCorrelation2) a SummarizedExperiment or an expression table as a DataFrame, data.frame or matrix object.

what The clustering level to be used for plotting and calculating correlations. Can be either "CTSS" to use individual TSSs or "consensusClusters" to use consen-
sus clusters, *i.e.* entire promoters. Ignored for anything else than CAGEr objects.

values
Use either "raw" (default) or "normalized" CAGE signal. Ignored for plain expression tables.

samples
Character vector indicating which samples to use. Can be either "all" to select all samples in a CAGEr object, or a subset of valid sample labels as returned by the `sampleLabels` function.

method
A character string indicating which correlation coefficient should be computed. Passed to `cor` function. Can be one of "pearson", "spearman", or "kendall".

tagCountThreshold
Only TSSs with tag count >= tagCountThreshold in either one (applyThresholdBoth = FALSE) or both samples (applyThresholdBoth = TRUE) are plotted and used to calculate correlation.

applyThresholdBoth
See `tagCountThreshold` above.

plotSize
Size of the individual comparison plot in pixels - the total size of the resulting png will be length(samples) * plotSize in both dimensions. Ignored in `plotCorrelation2`.

digits
The number of significant digits for the data to be kept in log scale. Ignored in `plotCorrelation`. In `plotCorrelation2`, the number of points plotted is considerably reduced by rounding the point coordinates to a small number of significant digits before removing duplicates. Chose a value that makes the plot visually indistinguishable with non-deduplicated data, by making tests on a subset of the data.

Details

In the scatter plots, a pseudo-count equal to half the lowest score is added to the null values so that they can appear despite logarithmic scale.

SummarizedExperiment objects are expected to contain raw tag counts in a “counts” assay and the normalized expression scores in a “normalized” assay.

Avoid using large matrix objects as they are coerced to DataFrame class without special care for efficiency.

`plotCorrelation2` speeds up the plotting by a) deduplicating that data: no point is plot twice at the same coordinates, b) rounding the data so that indistinguishable positions are plotted only once, c) using a black square glyph for the points, d) caching some calculations that are made repeatedly (to determine where to plot the correlation coefficients), and e) preventing coercion of DataFrames to data.frames.

Value
Displays the plot and returns a matrix of pairwise correlations between selected samples. The scatterplots of `plotCorrelation` are colored according to the density of points, and in `plotCorrelation2` they are just black and white, which is much faster to plot. Note that while the scatterplots are on a logarithmic scale with pseudocount added to the zero values, the correlation coefficients are calculated on untransformed (but thresholded) data.

Examples

```r
plotCorrelation2(exampleCAGEexp, what = "consensusClusters", value = "normalized")
```

---

**plotExpressionProfiles**

*Plotting expression profiles derived from CAGE data*

**Description**

Creates a chart with beanplots representing distribution of normalized expression across CAGE experiments for individual expression classes. Different expression classes are shown in different colors and are labeled according to the labels returned by expression clustering.

**Usage**

```r
plotExpressionProfiles(object, what)
```

**Arguments**

- `object` A `CAGEset` object.
- `what` Which level of expression clustering should be used. Can be either "CTSS" to plot expression profiles of individual CTSSs or "consensusClusters" to plot expression profiles of consensus clusters.

**Details**

The created file contains beanplots representing distribution of normalized expression across CAGE experiments for individual expression classes shown in separate boxes. Each labeled box represents one expression class and contains a set of beanplots - one per CAGE experiment. Individual CAGE experiments are shown on X-axis and scaled normalized expression on Y-axis. Individual beanplots show distribution of normalized expression values of elements belonging to specific expression class in particular CAGE experiment, and the entire box represents single expression profile. Different expression classes (boxes) are plotted in different colors and are labeled with labels returned by expression clustering.

plotExpressionProfiles(object = exampleCAGEset, what = "CTSS")
```

---

**plotInterquantileWidth**

*Plot cluster widths*

**Description**

Plots histograms of the interquantile width of tag clusters or consensus clusters in each CAGE dataset.

**Usage**

```r
plotInterquantileWidth(object, clusters = c("tagClusters", "consensusClusters"), tpmThreshold = 5, qLow = 0.1, qUp = 0.9, xlim = c(0, 150), ...)
```

### S4 method for signature 'CAGEr'

```r
plotInterquantileWidth(object, clusters = c("tagClusters", "consensusClusters"), tpmThreshold = 5, qLow = 0.1, qUp = 0.9, xlim = c(0, 150), ...)
```

**Arguments**

- `object`: A `CAGEr` object.
- `clusters`: Which clusters to be used. ("tagClusters" for tag clusters or "consensusClusters" for consensus clusters).
- `tpmThreshold`: Exclude clusters with normalized signal < tpmThreshold.
- `qLow`, `qUp`: Position of which "lower" (resp. "upper") quantile should be used as 5' (resp. 3') boundary. See Details.
- `xlim`: The x axis limits of the plot.
- `...`: Additional arguments passed to `plot()` function, such as `ylim`, etc.

**Details**

Interquantile width is a width (in base-pairs) of the central part of the genomic region (bounded by the positions of specified `qLow` and `qUp` quantiles) that contains \( \geq (qUp - qLow) \times 100\% \) of the CAGE signal. Positions of specified quantiles within each cluster have to be calculated beforehand by calling `quantilePositions` function. Interquantile width is a more robust measure of the promoter width than the total span of the region, because it takes into account the magnitude of the expression in the region.

plotInterquantileWidth(exampleCAGEexp, clusters = "consensusClusters", tpmThreshold = 50, qLow = 0.1, qUp = 0.9)

plotReverseCumulatives

Plot reverse cumulative number of CAGE tags per CTSS

Description
Plots the reverse cumulative distribution of the number of CAGE tags per CTSS for all CAGE datasets present in the CAGEr object. The plots should be used as help in choosing the parameters for power-law normalization: the range of values to fit the power-law and the slope of the referent power-law distribution (Balwierz et al., Genome Biology 2009).

Usage

plotReverseCumulatives(object, values = c("raw", "normalized"), fitInRange = c(10, 1000), onePlot = FALSE, main = NULL, legend = TRUE, xlab = "number of CAGE tags", ylab = "number of CTSSs (>= nr tags)", xlim = c(1, 1e+05), ylim = c(1, 1e+06))

## S4 method for signature 'CAGEr'
plotReverseCumulatives(object, values = c("raw", "normalized"), fitInRange = c(10, 1000), onePlot = FALSE, main = NULL, legend = TRUE, xlab = "number of CAGE tags", ylab = "number of CTSSs (>= nr tags)", xlim = c(1, 1e+05), ylim = c(1, 1e+06))
Arguments

- **object**: A CAGEr object
- **values**: Which values should be plotted: `raw` (default) for raw CAGE tag counts or normalized for normalized tag count values.
- **fitInRange**: An integer vector with two values specifying a range of tag count values to be used for fitting a power-law distribution to reverse cumulatives. Ignored if set to NULL. See Details.
- **onePlot**: Logical, should all CAGE datasets be plotted in the same plot (`TRUE`) or in separate plots (`FALSE`).
- **main**: Main title for the plot.
- **legend**: Set to `NULL` to prevent the display of the sample legend.
- **xlab, ylab**: Axis labels passed to `plot`.
- **xlim, ylim**: Axis range parameters passed to `plot`.

Details

Number of CAGE tags (X-axis) is plotted against the number of TSSs that are supported by >= of that number of tags (Y-axis) on a log-log scale for each sample. In addition, a power-law distribution is fitted to each reverse cumulative using the values in the range specified by `fitInRange` parameter. The fitted distribution is defined by \( y = -1 \times \alpha \times x + \beta \) on the log-log scale, and the value of \( \alpha \) for each sample is shown on the plot. In addition, a suggested referent power-law distribution to which all samples should be normalized is drawn on the plot and corresponding parameters (slope \( \alpha \) and total number of tags \( T \) ) are denoted on the plot. Referent distribution is chosen so that its slope (alpha) is the median of slopes fitted to individual samples and its total number of tags (T) is the power of 10 nearest to the median number of tags of individual samples. Resulting plots are helpful in deciding whether power-law normalization is appropriate for given samples and reported alpha values aid in choosing optimal alpha value for referent power-law distribution to which all samples will be normalized. For details about normalization see `normalizeTagCount` function.

Value

Plots of reverse cumulative number of CAGE tags per CTSS for each CAGE dataset within CAGEr object. Alpha values of fitted power-laws and suggested referent power-law distribution are reported on the plot in case `values = "raw"`.

quantilePositions

Determine CTSS quantile positions within clusters

Description

Calculates the positions of “upper” and “lower” quantiles of CAGE signal along tag clusters or consensus clusters in each sample of a CAGEr object.

Usage

quantilePositions(object, clusters = c("tagClusters", "consensusClusters"), qLow = 0.1, qUp = 0.9, useMulticore = FALSE, nrCores = NULL)

## S4 method for signature 'CAGEr'
quantilePositions(object, clusters = c("tagClusters", "consensusClusters"), qLow = 0.1, qUp = 0.9, useMulticore = FALSE, nrCores = NULL)

Arguments

object A CAGEr object.
clusters Either tagClusters or consensusClusters.
qLow, qUp Which “lower” or “upper” quantiles should be calculated. Numeric vector of values in range [0, 1].
useMulticore Logical, should multicore be used. useMulticore = TRUE has only effect on Unix-like platforms.
nrCores Number of cores to use when useMulticore = TRUE. Default value NULL uses all detected cores.

Details

From the 5' end the position, the position of a quantile \( q \) is determined as the first base in which of the cumulative expression is higher or equal to \( q\% \) of the total CAGE signal of that cluster. Promoter interquantile width is defined as the distance (in base pairs) between a “lower” and an “upper” quantile position.
quantilePositions

Value

When clusters = "tagClusters", the slots tagClustersQuantileLow and tagClustersQuantileUp of a provided CAGEset object will be occupied with the positions of specified quantiles in all tag clusters for all CAGE datasets. When clusters = "consensusClusters" the slots consensusClustersQuantileLow and consensusClustersQuantileUp will be occupied by the corresponding information for consensus clusters.

In CAGEexp objects, the positions of the quantiles are defined relatively to the start point of their cluster, for more efficient Rle compression. The quantile data for tag clusters are stored in the TagClusters objects directly. The quantile data for consensus clusters are stored in integer matrices named "q_\_x", where x represents the quantile (for instance, q_\_0.1), and these matrices are assays of the consensusClusters RangedSummarizedExperiment.

ranges2annot

Hierarchical annotation of CTSSes

Description

Assigns region types such as promoter, exon or unknown to CTSSes.

Usage

ranges2annot(ranges, annot)

Arguments

ranges  A CTSS object, for example extracted from a RangedSummarizedExperiment object with the rowRanges command.
annot  A GRanges from which promoter positions will be inferred. Typically GENCODE. If the type metadata is present, it should contain gene, exon and transcript among its values. Otherwise, all entries are considered transcripts. If the transcript_type metadata is available, the entries that may not be primary products (for instance 'snoRNA') are discarded.

Details

Only the biotypes that are likely to have a pol II promoter will be filtered in. This is currently hardcoded in the function; see its source code. Example of biotypes without a pol II promoter: VDJ segments, miRNA, but also snoRNA, etc. Thus, the Intergenic category displayed in output of the plotAnnot may include counts overlapping with real exons of discarded transcribed regions: be careful that large percentages do not necessarily suggest abundance of novel promoters.

Value

A Run-length-encoded (Rle) factor of same length as the CTSS object, indicating if the interval is promoter, exon, intron or unknown, or just promoter, gene, unknown if the type metadata is absent.

CAGEr:::ranges2annot(ctss, gr2)

ranges2genes

Description
Assign gene symbol(s) to Genomic Ranges.

Usage
ranges2genes(ranges, genes)

Arguments
ranges Genomics Ranges object, for example extracted from a RangedSummarizedExperiment object with the rowRanges command.
genes A GRanges object containing gene_name metadata.

Details
This private (non-exported) function is used to assign gene symbols to genomic ranges. It is run by annotateCTSS, which has to be run before CTSStoGenes.

Value
A Rle character vector of same length as the GRanges object, indicating one gene symbol or a semicolon-separated list of gene symbols for each range.

Author(s)
Charles Plessy

Description

Intersection of genomic ranges

Usage

ranges2names(rangesA, rangesB)

Arguments

rangesA  A GRanges object.
rangesB  A second GRanges object.

Details

This private (non-exported) function intersects two genomic ranges and for each element of the first object returns the name of the elements of the second object that it intersects with.

Value

A Rle character vector of same length as the rangesA GRanges object, indicating one name or a semicolon-separated list of names from each rangesB object.

**sampleLabels**

Get and set sample labels

**Description**

`sampleLabels` gets or sets the labels and colors of CAGE datasets (samples) from CAGEr objects. `sampleList` is an accessory function for convenience iteration in functions such as `lapply` or `mapply`. There is no set method for `sampleList`.

**Usage**

```r
sampleLabels(object)
## S4 method for signature 'CAGEset'
sampleLabels(object)
## S4 method for signature 'CAGEexp'
sampleLabels(object)
## S4 method for signature 'CTSS'
sampleLabels(object)

sampleList(object)
## S4 method for signature 'CAGER'
sampleList(object)

sampleLabels(object) <- value
## S4 replacement method for signature 'CAGEset'
sampleLabels(object) <- value
## S4 replacement method for signature 'CAGEexp'
sampleLabels(object) <- value
## S4 replacement method for signature 'CTSS'
sampleLabels(object) <- value
```

**Arguments**

- **object**
  A CAGEr object.
- **value**
  A character vector with a unique and valid name for each sample. The names attributes indicate the colors.

**Details**

In CAGEexp objects, renaming samples is possible only before data is loaded.
Value

sampleLabels returns a named character vector representing labels of all CAGE datasets present in the CAGEr object. The vector values are the labels and the vector names are the colors.
sampleList returns a named list where elements and their names are the sample names, for instance: list(sampleA = "sampleA", sampleB = "sampleB"). Thus, after iterating on it with lapply, the element names will be sample names.

Note

If no colors are supplied, then default colors will be assigned using the rainbow function. Assigned colors are not guaranteed to be stable.

scoreShift Calculate promoter shifting score

Description

Calculates the shifting score for all consensus clusters (promoters) between two specified (groups of) CAGE datasets. Shifting score is a measure of differential usage of TSSs within consensus cluster between two samples, which indicates the degree of physical separation of TSSs used in these samples within given consensus cluster. In addition to shifting score, a statistical significance (P-value and FDR) of differential TSS usage is calculated for each consensus cluster using Kolmogorov-Smirnov test.

Usage

scoreShift(object, groupX, groupY, testKS = TRUE, useTpmKS = TRUE, useMulticore = F, nrCores = NULL)

## S4 method for signature 'CAGEset'
scoreShift(object, groupX, groupY, testKS = TRUE, useTpmKS = TRUE, useMulticore = F, nrCores = NULL)
scoreShift

Arguments

- **object**: A CAGER object.
- **groupX, groupY**: Character vector of the one or more CAGE dataset labels in the first (groupX) and in the second group (groupY). Shifting score for each consensus cluster will be calculated by comparing CAGE signal in the samples from groupX against the signal in the samples from groupY. If there is more than one CAGE dataset in the group, the datasets within that group will be merged together before comparison with the other group. See Details.
- **testKS**: Logical, should Kolomogorov-Smirnov test for statistical significance of differential TSS usage be performed, and P-values and FDR returned. See Details.
- **useTpmKS**: Logical, should normalized (tpm) values (TRUE) or raw tag counts (FALSE) be used to derive sample sizes for Kolomogorov-Smirnov test. Used only when testKS = TRUE, otherwise ignored. See Details.
- **useMulticore**: Logical, should multicore be used. useMulticore = TRUE is supported only on Unix-like platforms.
- **nrCores**: Number of cores to use when useMulticore = TRUE. Default value NULL uses all detected cores.

Details

TSSs within one consensus cluster (promoter) can be used differently in different samples (cell types, tissues, developmental stages), with respect to their position and frequency of usage detected by CAGE. This function calculates shifting scores of all consensus clusters between two specified (groups of) CAGE samples to detect promoters that are used differently in these two samples. Shifting score is a measure of differential TSS usage defined as:

\[
\text{score} = \frac{\text{max}(F1 - F2)}{\text{max}(F1)}
\]

where \( F1 \) is a cumulative sum of CAGE signal along consensus cluster in the group of samples with lower total signal in that consensus cluster, and \( F2 \) in the opposite group. Since cumulative sum can be calculated in both forward (5' -> 3') and reverse (3' -> 5') direction, shifting score is calculated for both cases and the bigger value is selected as final shifting score. Value of the shifting score is in the range \([-\infty, 1]\), where value of 1 means complete physical separation of TSSs used in the two samples for given consensus cluster. In general, any non-negative value of the shifting score can be interpreted as the proportion of transcription initiation in the sample with lower expression that is happening "outside" (either upstream or downstream) of the region used for transcription initiation in the other sample. Negative values indicate no physical separation, i.e. the region used for transcription initiation in the sample with lower expression is completely contained within the region used for transcription initiation in the other sample.

In addition to shifting score which indicates only physical separation (upstream or downstream shift of TSSs), a more general assessment of differential TSS usage can be obtained by performing a two-sample Kolmogorov-Smirnov test on cumulative sums of CAGE signal along the consensus cluster. In that case, cumulative sums in both samples are scaled to range \([0, 1]\) and are considered to be empirical cumulative distribution functions (ECDF) reflecting sampling of TSS positions during transcription initiation. Kolmogorov-Smirnov test is performed to assess whether the two underlying probability distributions differ. To obtain P-value (i.e. the level at which the null-hypothesis can be rejected), sample sizes that generated the ECDFs are required, in addition to actual K-S statistics calculated from ECDFs. These are derived either from raw tag counts, i.e. exact number of times each TSS in the cluster was sampled during sequencing (when useTpmKS = FALSE), or from normalized tpm values (when useTpmKS = TRUE). P-values obtained from K-S tests are further adjusted for multiple testing using Benjamini & Hochberg (BH) method and for each P-value a corresponding false-discovery rate (FDR) is also reported.
Since calculation of shifting scores and Kolmogorov-Smirnov test require cumulative sums along consensus clusters, they have to be calculated beforehand by calling `cumulativeCTSSdistribution` function.

The slots `shiftingGroupX`, `shiftingGroupY` and `consensusClustersShiftingScores` of the provided `CAGEset` object will be occupied by the information on the groups of CAGE datasets that have been compared and shifting scores of all consensus clusters. Consensus clusters (promoters) with shifting score and/or FDR above specified threshold can be extracted by calling `getShiftingPromoters` function.

```

Description

Methods for function `show`.

Methods

`signature(object = "CAGEset")` Displays a CAGEset object in a user-friendly way, giving an overview of its content.

Strand invaders

Detect and remove strand invasion artefacts

Description

`findStrandInvaders` detects strand invasion artefacts in the CTSS data. `removeStrandInvaders` removes them.

*Strand invaders* are artefacts produced by *template switching* reactions used in methods such as *nanoCAGE* and its derivatives (*C1 CAGE*, ...). They are described in details in Tang et al., 2013. Briefly, these artefacts create CAGE-like signal downstream of genome sequences highly similar to the tail of template-switching oligonucleotides, which is TATAGG in recent (2017) nanoCAGE protocols. Since these artefacts represent truncated cDNAs, they do not indicate promoter regions. It is therefore advisable to remove these artefacts. Moreover, when a sample barcode is near the linker sequence (which is not the case in recent nanoCAGE protocols), the strand-invasion artefacts can produce *sample-specific biases*, which can be confounded with biological effects depending on how the barcode sequences were chosen. A barcode parameter is provided to incorporate this information.
Usage

```r
findStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")
```

```r
removeStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")
```

## S4 method for signature 'CAGEexp'
findStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")

## S4 method for signature 'CAGEexp'
removeStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")

## S4 method for signature 'CTSS'
findStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")

## S4 method for signature 'CTSS'
removeStrandInvaders(object, distance = 1, barcode = NULL, linker = "TATAGGG")

Arguments

- **object**: A `CAGEexp` object containing CTSS data and the name of a reference genome.
- **distance**: The maximal edit distance between the genome and linker sequences. Regardless this parameter, only a single mismatch is allowed in the last three bases of the linker.
- **barcode**: A vector of sample barcode sequences, or the name of a column metadata of the `CAGEexp` object containing this information. *(Not implemented yet)*
- **linker**: The sequence of the tail of the template-switching oligonucleotide, that will be matched with the genome sequence (defaults to `TATAGGG`).

Value

`findStrandInvaders` returns a logical-Rle vector indicating the position of the strand invaders in the input ranges. With `CTSS` objects as input `removeStrandInvaders` returns the object after removing the CTSS positions identified as strand invaders. In the case of `CAGEexp` objects, the input object is modified in place. Its sample metadata is also updated by creating a new `strandInvaders` column that indicates the number of molecule counts removed. This value is subtracted from the `counts` column so that the total number of tags is still equal to `librarySizes`.

```

**Arguments**

- `gr` Consensus clusters in GRanges format.
- `df` Consensus clusters in data.frame format.

**Details**

The original format used in CAGEset objects follows BED ("0-based") convention for the start and end coordinates. On the other hand, the GRanges objects used in CAGEexp objects follow the "1-based" convention. Therefore a value of 1 has to be added or subtracted to the start positions when converting between both formats.

**See Also**

Other df2granges converters: `consensusClusterConvertors`

**Examples**

```r
df <- tagClusters(exampleCAGEset, 1)
head(df)
gr <- CAGEr:::TCdataframe2granges(df)
head(CAGEr:::TCgranges2dataframe(gr))
# No exact round-trip because start and end were not integer in df.
if (! all(df == CAGEr:::TCgranges2dataframe(gr)))
  stop("No round-trip between Tdataframe2granges and TCgranges2dataframe")
tagClustersGR(exampleCAGEexp)
head(CAGEr:::TCgranges2dataframe(CAGEr:::tagClustersGR(exampleCAGEexp, 1)))
```
tagClusters

Extract tag clusters (TCs) for individual CAGE experiments

Description

Extraction of tag clusters (TCs) produced by the `clusterCTSS` function for a specified CAGE experiment from a CAGEr object.

Usage

tagClusters(object, samples = NULL, returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

## S4 method for signature 'CAGEr'
tagClusters(object, samples = NULL, returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

tagClustersGR(object, sample = NULL, returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

## S4 method for signature 'CAGEset'
tagClustersGR(object, sample = NULL, returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

## S4 method for signature 'CAGEexp'
tagClustersGR(object, sample = NULL, returnInterquantileWidth = FALSE, qLow = NULL, qUp = NULL)

tagClustersGR(object, samples = NULL) <- value

## S4 replacement method for signature 'CAGEset,ANY,ANY'
tagClustersGR(object, samples = NULL) <- value

## S4 replacement method for signature 'CAGEexp,ANY,TagClusters'
tagClustersGR(object, samples = NULL) <- value

## S4 replacement method for signature 'CAGEexp,missing,GRangesList'
tagClustersGR(object, samples = NULL) <- value

Arguments

object A CAGEr object.
samples Label of the CAGE dataset (experiment, sample) for which to extract tag clusters. If samples = NULL, a list of all the clusters for each sample is returned.
returnInterquantileWidth Should the interquantile width for each tag cluster be returned.
tagClustersQuantile

qLow, qUp  Position of which quantile should be used as a left (lower) or right (upper) boundary (for qLow and qUp respectively) when calculating interquantile width. Default value NULL results in using the start coordinate of the cluster. Used only when returnInterquantileWidth = TRUE, otherwise ignored.

sample  Label of one CAGE dataset (experiment, sample) for which to extract tag clusters. (For tagClustersGR, only one sample can be extracted.)

value  A TagClusters object.

Value

Returns a data.frame with genomic coordinates, position of dominant TSS, total CAGE signal and additional information for all TCs from specified CAGE dataset (sample). If returnInterquantileWidth = TRUE, interquantile width for each TC is also calculated using specified quantile positions and returned in the data frame.

Author(s)

Vanja Haberle

tagClustersQuantileLow(object, samples = NULL, q = NULL)
tagClustersQuantileUp(object, samples = NULL, q = NULL)
## S4 method for signature 'CAGEset'
tagClustersQuantileUp(object, samples = NULL, q = NULL)
## S4 method for signature 'CAGEexp'
tagClustersQuantileUp(object, samples = NULL, q = NULL)
tagClustersQuantileLow(object, samples = NULL) <- value
## S4 replacement method for signature 'CAGEset'
tagClustersQuantileLow(object, samples = NULL) <- value
## S4 replacement method for signature 'CAGEexp'
tagClustersQuantileLow(object, samples = NULL) <- value
## S4 replacement method for signature 'CAGEset'
tagClustersQuantileUp(object, samples = NULL) <- value
## S4 replacement method for signature 'CAGEexp'
tagClustersQuantileLow(object, samples = NULL) <- value

Arguments

object A CAGEr object.
samples Sample name(s), number(s) or NULL (default) for all samples.
q A single quantile (not a list)
value A list (one entry per sample) of data frames with multiple columns: cluster for the cluster ID, and then q_0.n where 0.n indicates a quantile.
Value

Returns a data frame where the first column gives cluster names and the next columns give quantile positions, in zero-based chromosome coordinates (because the tag clusters in CAGEset objects are represented in zero-based coordinates as well).
