

Package ‘GSVA’

November 22, 2017

Version 1.26.0

Title Gene Set Variation Analysis for microarray and RNA-seq data

Depends R (>= 3.0.0)

Imports methods, BiocGenerics, Biobase, GSEABase (>= 1.17.4),
geneplotter, shiny, shinythemes

Suggests limma, RColorBrewer, genefilter, mclust, edgeR, snow,
parallel, GSVAdata

Description Gene Set Variation Analysis (GSVA) is a non-parametric, unsupervised method for estimating variation of gene set enrichment through the samples of a expression data set. GSVA performs a change in coordinate systems, transforming the data from a gene by sample matrix to a gene-set by sample matrix, thereby allowing the evaluation of pathway enrichment for each sample. This new matrix of GSVA enrichment scores facilitates applying standard analytical methods like functional enrichment, survival analysis, clustering, CNV-pathway analysis or cross-tissue pathway analysis, in a pathway-centric manner.

`computeGeneSetsOverlap`*Compute gene-sets overlap*

Description

Calculates the overlap among every pair of gene-sets given as input.

Usage

```
## S4 method for signature 'list,character'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'list,ExpressionSet'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection,character'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection,ExpressionSet'  
computeGeneSetsOverlap(gSets, uniqGenes, min.sz=1, max.sz=Inf)
```

Arguments

<code>gSets</code>	Gene sets given either as a list or a GeneSetCollection object.
<code>uniqGenes</code>	Vector of unique genes to be considered when calculating the overlaps.
<code>min.sz</code>	Minimum size.
<code>max.sz</code>	Maximum size.

Details

This function calculates the overlap between every pair of gene sets of the input argument `gSets`. Before this calculation takes place, the gene sets in `gSets` are firstly filtered to discard genes that do not match to the identifiers in `uniqGenes`. Secondly, they are further filtered to meet the minimum and/or maximum size specified with the arguments `min.sz` and `max.sz`. The overlap between two gene sets is calculated as the number of common genes between the two gene sets divided by the smallest size of the two gene sets.

Value

A gene-set by gene-set matrix of the overlap among every pair of gene sets.

[filterGeneSets](#)

Examples

```
geneSets <- list(set1=as.character(1:4), set2=as.character(4:10))  
  
computeGeneSetsOverlap(geneSets, unique(unlist(geneSets)))
```

filterGeneSets	<i>Filter gene sets</i>
----------------	-------------------------

Description

Filters gene sets through a given minimum and maximum set size.

Usage

```
## S4 method for signature 'list'  
filterGeneSets(gSets, min.sz=1, max.sz=Inf)  
## S4 method for signature 'GeneSetCollection'  
filterGeneSets(gSets, min.sz=1, max.sz=Inf)
```

Arguments

gSets	Gene sets given either as a list or a GeneSetCollection object.
min.sz	Minimum size.
max.sz	Maximum size.

Details

This function filters the input gene sets according to a given minimum and maximum set size.

Value

A collection of gene sets that meet the given minimum and maximum set size.

      kernel=TRUE,
      ssgsea.norm=TRUE,
      verbose=TRUE,
      return.old.value=FALSE)

```

Arguments

<code>expr</code>	Gene expression data which can be given either as an <code>ExpressionSet</code> object or as a matrix of expression values where rows correspond to genes and columns correspond to samples.
<code>gset.idx.list</code>	Gene sets provided either as a <code>list</code> object or as a <code>GeneSetCollection</code> object.
<code>annotation</code>	In the case of calling <code>gsva()</code> with expression data in a matrix and gene sets as a <code>GeneSetCollection</code> object, the <code>annotation</code> argument can be used to supply the name of the Bioconductor package that contains annotations for the class of gene identifiers occurring in the row names of the expression data matrix. By default <code>gsva()</code> will try to match the identifiers in <code>expr</code> to the identifiers in <code>gset.idx.list</code> just as they are, unless the <code>annotation</code> argument is set.
<code>method</code>	Method to employ in the estimation of gene-set enrichment scores per sample. By default this is set to <code>gsva</code> (Hänzelmann et al, 2013) and other options

are *ssgsea* (Barbie et al, 2009), *zscore* (Lee et al, 2008) or *plage* (Tomfohr et al, 2005). The latter two standardize first expression profiles into z-scores over the samples and, in the case of *zscore*, it combines them together as their sum divided by the square-root of the size of the gene set, while in the case of *plage* they are used to calculate the singular value decomposition (SVD) over the genes in the gene set and use the coefficients of the first right-singular vector as pathway activity profile.

<code>kcdf</code>	Character string denoting the kernel to use during the non-parametric estimation of the cumulative distribution function of expression levels across samples when <code>method="gsva"</code> . By default, <code>kcdf="Gaussian"</code> which is suitable when input expression values are continuous, such as microarray fluorescent units in logarithmic scale, RNA-seq log-CPMs, log-RPKMs or log-TPMs. When input expression values are integer counts, such as those derived from RNA-seq experiments, then this argument should be set to <code>kcdf="Poisson"</code> . This argument supersedes arguments <code>rnaseq</code> and <code>kernel</code> , which are deprecated and will be removed in the next release.
<code>rnaseq</code>	This argument has been deprecated and will be removed in the next release. Please use the argument <code>kcdf</code> instead.
<code>abs.ranking</code>	Flag used only when <code>mx.diff=TRUE</code> . When <code>abs.ranking=FALSE</code> (default) a modified Kuiper statistic is used to calculate enrichment scores, taking the magnitude difference between the largest positive and negative random walk deviations. When <code>abs.ranking=TRUE</code> the original Kuiper statistic that sums the largest positive and negative random walk deviations, is used. In this latter case, gene sets with genes enriched on either extreme (high or low) will be regarded as 'highly' activated.
<code>min.sz</code>	Minimum size of the resulting gene sets.
<code>max.sz</code>	Maximum size of the resulting gene sets.
<code>no.bootstraps</code>	Number of bootstrap iterations to perform. This argument has been deprecated and will be removed in the next release.
<code>bootstrap.percent</code>	.632 is the ideal percent samples bootstrapped. This argument has been deprecated and will be removed in the next release.
<code>parallel.sz</code>	Number of processors to use when doing the calculations in parallel. This requires to previously load either the <code>parallel</code> or the <code>snow</code> library. If <code>parallel</code> is loaded and this argument is left with its default value (<code>parallel.sz=0</code>) then it will use all available core processors unless we set this argument with a smaller number. If <code>snow</code> is loaded then we must set this argument to a positive integer number that specifies the number of processors to employ in the parallel calculation.
<code>parallel.type</code>	Type of cluster architecture when using <code>snow</code> .
<code>mx.diff</code>	Offers two approaches to calculate the enrichment statistic (ES) from the KS random walk statistic. <code>mx.diff=FALSE</code> : ES is calculated as the maximum distance of the random walk from 0. <code>mx.diff=TRUE</code> (default): ES is calculated as the magnitude difference between the largest positive and negative random walk deviations.
<code>tau</code>	Exponent defining the weight of the tail in the random walk performed by both the <i>gsva</i> (Hänzelmann et al., 2013) and the <i>ssgsea</i> (Barbie et al., 2009) methods. By default, this <code>tau=1</code> when <code>method="gsva"</code> and <code>tau=0.25</code> when <code>method="ssgsea"</code> just as specified by Barbie et al. (2009) where this parameter is called alpha.

kernel	This argument has been deprecated and will be removed in the next release. Please use the argument <code>kcdf</code> instead.
ssgsea.norm	Logical, set to TRUE (default) with <code>method="ssgsea"</code> runs the SSGSEA method from Barbie et al. (2009) normalizing the scores by the absolute difference between the minimum and the maximum, as described in their paper. When <code>ssgsea.norm=FALSE</code> this last normalization step is skipped.
verbose	Gives information about each calculation step. Default: FALSE.
return.old.value	Logical, set to FALSE (default) has no effect but when <code>return.old.value=TRUE</code> , then the return value takes form of a <code>list</code> object as in previous versions of GSVA. This argument will be present only in this release for backward compatibility purposes during the deprecation of the arguments <code>no.bootstraps</code> and <code>bootstrap.percent</code> and will disappear in the next release.

Details

GSVA assesses the relative enrichment of gene sets across samples using a non-parametric approach. Conceptually, GSVA transforms a p-gene by n-sample gene expression matrix into a g-geneset by n-sample pathway enrichment matrix. This facilitates many forms of statistical analysis in the 'space' of pathways rather than genes, providing a higher level of interpretability.

The `gsva()` function first maps the identifiers in the gene sets to the identifiers in the input expression data leading to a filtered collection of gene sets. This collection can be further filtered to require a minimum and/or maximum size of the gene sets for which we want to calculate GSVA enrichment scores, by using the arguments `min.sz` and `max.sz`.

Value

A gene-set by sample matrix of GSVA enrichment scores.

## estimate moderated t-statistics
fit <- eBayes(fit)

## genes in set1 are differentially expressed
topTable(fit, coef="sampleGroup2vs1")

## estimate GSVa enrichment scores for the three sets
gsva_es <- gsva(y, geneSets, mx.diff=1)

## fit the same linear model now to the GSVa enrichment scores
fit <- lmFit(gsva_es, design)

## estimate moderated t-statistics
fit <- eBayes(fit)

## set1 is differentially expressed
topTable(fit, coef="sampleGroup2vs1")

```

Description

Starts an interactive GSVa shiny web app.

Usage

```
igsva()
```

Details

GSVA assesses the relative enrichment of gene sets across samples using a non-parametric approach. Conceptually, GSVA transforms a p-gene by n-sample gene expression matrix into a g-geneset by n-sample pathway enrichment matrix. This facilitates many forms of statistical analysis in the 'space' of pathways rather than genes, providing a higher level of interpretability.

The `igsva()` function starts an interactive shiny web app that allows the user to configure the arguments of the `gsva()` function and runs it on the computer. Please see the manual page of the `gsva()` function for a description of the arguments and their default and alternative values.

The input data may be loaded from the users workspace or by selecting a CSV file for the expression data, and a GMT file for the gene sets data.

Value

A gene-set by sample matrix of GSVA enrichment scores after pressing the button 'Save & Close'. This result can be also downloaded as a CSV file with the 'Download' button.
