1 Scope

BiocParallel enables use of random number streams in a reproducible manner. This document applies to the following *Param():

- **SerialParam()**: sequential evaluation in a single R process.
- **SnowParam()**: parallel evaluation in multiple independent R processes.
- **MulticoreParam()**: parallel evaluation in R sessions running in forked threads. Not available on Windows.

The *Param() can be used for evaluation with:

- **bplapply()**: lapply()-like application of a user-supplied function FUN to a vector or list of elements X.

- **bpiterate()**: apply a user-supplied function FUN to an unknown number of elements resulting from successive calls to a user-supplied function ITER.

The reproducible random number implementation also supports:

- **bptry()** and the BPRED0= argument, for re-evaluation of elements that fail (e.g., because of a bug in FUN).
2 Essentials

2.1 Use of `bplapply()` and RNGseed=

Attach `BiocParallel` and ensure that the version is greater than 1.27.5

```r
library(BiocParallel)
stopifnot(
    packageVersion("BiocParallel") > "1.27.5"
)
```

For reproducible calculation, use the `RNGseed=` argument in any of the `*Param()` constructors.

```r
result1 <- bplapply(1:3, runif, BPPARAM = SerialParam(RNGseed = 100))
result1
## [[1]]
## [1] 0.7393338
##
## [[2]]
## [1] 0.8216743 0.7451087
##
## [[3]]
## [1] 0.1962909 0.5226640 0.6857650
```

Repeating the calculation with the same value for `RNGseed=` results in the same result; a different random number seed results in different results.

```r
result2 <- bplapply(1:3, runif, BPPARAM = SerialParam(RNGseed = 100))
stopifnot(
    identical(result1, result2)
)
result3 <- bplapply(1:3, runif, BPPARAM = SerialParam(RNGseed = 200))
result3
## [[1]]
## [1] 0.9757768
##
## [[2]]
## [1] 0.6525851 0.6416909
##
## [[3]]
## [1] 0.6710576 0.5895330 0.7686983
stopifnot(
    !identical(result1, result3)
)
```

Results are invariant across `*Param()`

```r
result4 <- bplapply(1:3, runif, BPPARAM = SnowParam(RNGseed = 100))
stopifnot(
    identical(result1, result4)
)
```
Random Numbers in BiocParallel

```r
if (!identical(.Platform$OS.type, "windows")) {
  result5 <- bplapply(1:3, runif, BPPARAM = MulticoreParam(RNGseed = 100))
  stopifnot(
    identical(result1, result5)
  )
}
```

Parallel backends can adjust the number of workers (processes performing the evaluation) and tasks (how elements of \( X \) are distributed between workers). Results are invariant to these parameters. This is illustrated with SnowParam(), but applies also to MulticoreParam().

```r
result6 <- bplapply(1:3, runif, BPPARAM = SnowParam(workers = 2, RNGseed = 100))
result7 <- bplapply(1:3, runif, BPPARAM = SnowParam(workers = 3, RNGseed = 100))
result8 <- bplapply(
  1:3, runif,
  BPPARAM = SnowParam(workers = 2, tasks = 3, RNGseed = 100)
)
stopifnot(
  identical(result1, result6),
  identical(result1, result7),
  identical(result1, result8)
)
```

Subsequent sections illustrate results with SerialParam(), but identical results are obtained with SnowParam() and MulticoreParam().

2.2 Use with bpiterate()

bpiterate() allows parallel processing of a 'stream' of data as a series of tasks, with a task consisting of a portion of the overall data. It is useful when the data size is not known or easily partitioned into elements of a vector or list. A real use case might involve iterating through a BAM file, where a task represents successive records (perhaps 100,000 per task) in the file. Here we illustrate with a simple example – iterating through a vector \( x = 1:3 \)

```r
ITER_FUN_FACTORY <- function() {
  x <- 1:3
  i <- 0L
  function() {
    i <<- i + 1L
    if (i > length(x))
      return(NULL)
    x[i]
  }
}
```

ITER_FUN_FACTORY() is used to create a function that, on each invocation, returns the next task (here, an element of \( x \); in a real example, perhaps 100000 records from a BAM file). When there are no more tasks, the function returns NULL.
Random Numbers in BiocParallel

```r
ITER <- ITER_FUN_FACTORY()
ITER()
## [1] 1
ITER()
## [1] 2
ITER()
## [1] 3
ITER()
## NULL
```

In our simple example, `bpiterate()` is performing the same computations as `bplapply()` so the results, including the random number streams used by each task in `bpiterate()`, are the same.

```r
result9 <- bpiterate(
  ITER_FUN_FACTORY(), runif,
  BPPARAM = SerialParam(RNGseed = 100)
)
stopifnot(
  identical(result1, result9)
)
```

2.3 Use with `bptry()`

`bptry()` in conjunction with the `BPREDON` argument to `bplapply()` or `bpiterate()` allows for graceful recovery from errors. Here a buggy `FUN1()` produces an error for the second element. `bptry()` allows evaluation to continue for other elements of `X`, despite the error. This is shown in the result.

```r
FUN1 <- function(i) {
  if (identical(i, 2L)) {
    ## error when evaluating the second element
    stop("i == 2")
  } else runif(i)
}
result10 <- bptry(bplapply(
  1:3, FUN1,
  BPPARAM = SerialParam(RNGseed = 100, stop.on.error = FALSE)
))
result10
## [[1]]
## [1] 0.7393338
##
## [[2]]
## <remote_error in FUN(...): i == 2>
## traceback() available as 'attr(x, "traceback")'
##
```
## Random Numbers in BiocParallel

**FUN2** illustrates the flexibility of `bptry()` by fixing the bug when `i == 2`, but also generating incorrect results if invoked for previously correct values. The identity of the result to the original computation shows that only the error task is re-computed, and that the random number stream used by the task is identical to the original stream.

```r
FUN2 <- function(i) {
  if (identical(i, 2L)) {
    ## the random number stream should be in the same state as the
    ## first time through the loop, and rnorm(i) should return
    ## same result as FUN
    runif(i)
  } else {
    ## if this branch is used, then we are incorrectly updating
    ## already calculated elements -- '0' in the output would
    ## indicate this error
    0
  }
}
result11 <- bplapply(1:3, FUN2, BPREDO = result10, BPPARAM = SerialParam(RNGseed = 100, stop.on.error = FALSE))
stopifnot(identical(result1, result11))
```

### 2.4 Relationship between `RNGseed=` and `set.seed()`

The global random number stream (influenced by `set.seed()` is ignored by `BiocParallel`, and `BiocParallel` does NOT increment the global stream.

```r
set.seed(200)
value <- runif(1)
set.seed(200)
result12 <- bplapply(1:3, runif, BPPARAM = SerialParam(RNGseed = 100))
stopifnot(identical(result1, result12), identical(value, runif(1))
```

When `RNGseed=` is not used, an internal stream (not accessible to the user) is used and `BiocParallel` does NOT increment the global stream.
Random Numbers in BiocParallel

```r
set.seed(100)
value <- runif(1)
set.seed(100)
result13 <- bplapply(1:3, runif, BPPARAM = SerialParam())
stopifnot(
    !identical(result1, result13),
    identical(value, runif(1))
)
```

### 2.5 `bpstart()` and random number streams

In all of the examples so far `Param()` objects are passed to `bplapply()` or `bpiterate()` in the 'stopped' state. Internally, `bplapply()` and `bpiterate()` invoke `bpstart()` to establish the computational environment (e.g., starting workers for `SnowParam()`). `bpstart()` can be called explicitly, e.g., to allow workers to be used across calls to `bplapply()`.

The cluster random number stream is initiated with `bpstart()`. Thus

```r
param <- bpstart(SerialParam(RNGseed = 100))
result16 <- bplapply(1:3, runif, BPPARAM = param)
bpstop(param)
stopifnot(
    identical(result1, result16)
)
```

This allows a second call to `bplapply` to represent a continuation of a random number computation – the second call to `bplapply()` results in different random number streams for each element of `X`.

```r
param <- bpstart(SerialParam(RNGseed = 100))
result16 <- bplapply(1:3, runif, BPPARAM = param)
result17 <- bplapply(1:3, runif, BPPARAM = param)
bpstop(param)
stopifnot(
    identical(result1, result16),
    !identical(result1, result17)
)
```

### 2.6 Relationship between `bplapply()` and `lapply()`

The results from `bplapply()` are different from the results from `lapply()`, even with the same random number seed. This is because correctly implemented parallel random streams require use of a particular random number generator invoked in specific ways for each element of `X`, as outlined in the Implementation notes section.

```r
set.seed(100)
result20 <- lapply(1:3, runif)
stopifnot(
    !identical(result1, result20)
)
```
3 Implementation notes

The implementation uses the L’Ecuyer-CMRG random number generator (see ?RNGkind and ?parallel:::clusterSetRNGStream for additional details). This random number generates independent streams and substreams of random numbers. In BiocParallel, each call to bpstart() creates a new stream from the L’Ecuyer-CMRG generator. Each element in bapply() or biterate() creates a new substream. Each application of FUN is therefore using the L’Ecuyer-CMRG random number generator, with a substream that is independent of the substreams of all other elements.

Within the user-supplied FUN of bapply() or biterate(), it is a mistake to use RNGkind() to set a different random number generator, or to use set.seed(). This would in principle compromise the independence of the streams across elements.
