Package ‘ChIPsim’

May 2, 2024

Type Package
Title Simulation of ChIP-seq experiments
Version 1.58.0
Date 2011-05-18
Author Peter Humburg
Maintainer Peter Humburg <Peter.Humburg@gmail.com>
Description A general framework for the simulation of ChIP-seq data. Although currently focused on nucleosome positioning the package is designed to support different types of experiments.
License GPL (>= 2)

This package provides a framework for the simulation of ChIP-seq experiments. An implementation of a simulation for nucleosome positioning experiments is provided as part of the package. Simulations for other experiments can be implemented using the provided framework.
Function `simChIP` is the main driver of the simulation. To simulate different types of experiments the functions passed to the functions argument of `simChIP` have to be replaced. See the vignettes for more detail.

Author(s)

`ShortRead` and its dependencies are used to handle short read and genomic sequences.

Examples

```
## See the accompanying vignette 'Introduction to ChIPsim' for a detailed
## example of how to use this package for nucleosome positioning simulations.
## A guide for the writing of extensions that cover other types of
## experiments is provided in 'Extending ChIPsim'.
```

bindDens2readDens  

_Convert a feature density into a read density_

Description

Given a feature density this function produces two read densities, one for each strand.

Usage

```
bindDens2readDens(bindDens, fragment, nfrag = 1e+05, bind = 147,
minLength = 150, maxLength = 180, ...)
```

Arguments

bindDens Numeric vector with the feature density for one chromosome.
fragment Function giving the fragment length distribution.
nfrag Number of fragments that should be simulated to generate the read distribution.
bind Length of binding site.
minLength Minimum fragment length.
maxLength Maximum fragment length.
... Further arguments to `fragment`.
decodeQuality

Value
A two column matrix. The first column contains the read density for the forward strand, the second column the read density for the reverse strand.

Author(s)
Peter Humburg

See Also
feat2dens, sampleReads

Examples

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate feature density
featureDens <- feat2dens(features, length=1e5)

## convert to read density
readDens <- bindDens2readDens(featureDens, fragDens, meanLength=160)
```

decodeQuality Conversion between numerical and ASCII representation of read qualities

Description
These functions convert an ASCII encoded sequence of read qualities into a numeric vector of error probabilities and vice versa.

Usage

```r
decodeQuality(quality, type = c("Illumina", "Sanger", "Solexa"))
encodeQuality(quality, type = c("Illumina", "Sanger", "Solexa"))
```

Arguments

- **quality** For decodeQuality a character string representing the read qualities for a single sequence read. For encodeQuality a numeric vector of error probabilities.
- **type** Type of encoding to use.

Details
See extractQuality for a description of the currently supported encodings.
defaultControl

Description

Produces a list of parameters for each of the functions used to carry out the various stages of the simulation.

Usage

defaultControl(features = list(), bindDensity = list(), readDensity = list(), readNames = list(), readSequence = list())

Arguments

features Parameters for feature generation.
bindDensity Parameters for the conversion of feature sequence into binding site densities.
readDensity Parameters for the conversion of binding site densities into read densities. Always provides parameters
  fragment Default: fragDens
  meanLength Default: 160
readNames Parameters for the generation of read names.
readSequence  Parameters for the conversion of read positions into read sequences. Always
provides parameters
qualityFun  readQualitySample
errorFun  readError
readLen  36

Details
Any parameters passed as part of list to one of the arguments of defaultControl will be passed on
to the corresponding function in simChIP. The build-in defaults can be overwritten by providing a
list entry with the same name.

Value
List of parameters for use as the control argument to simChIP.

Author(s)
Peter Humburg

See Also
defaultFunctions, simChIP

Examples

defaultControl()
defaultControl(features=list(maxTail=0), readSequence=list(readLen=50))

defaultErrorProb  Replacement probabilities for sequencing errors

Description
For each nucleotide this function provides probabilities indicating how likely it is to be replaced by
any of the other nucleotides should a sequencing error occur.

Usage
defaultErrorProb()

Details
The probabilities used here are the ones determined by Dohm et al. for Beta vulgaris. They should
be more appropriate than a uniform distribution but the use of species specific rates is recommended
where available.
Value

A list of four vectors with replacement probabilities for each nucleotide.

Author(s)

Peter Humburg

References

Examples

```r
defaultErrorProb()
```

---

**Description**

Provides default functions to carry out the different stages of the ChIP-seq simulation.

**Usage**

```r
defaultFunctions()
```

**Value**

A list with components

- `features` (placeFeatures)
- `bindDensity` (feat2dens)
- `readDensity` (bindDens2readDens)
- `sampleReads` (sampleReads)
- `readSequence` (writeReads)
- `readNames` (simpleNames)

Author(s)

Peter Humburg

Examples

defaultFunctions()

defaultGenerator

Description

Functions to generate defaults for `makeFeatures`.

Usage

```r
defaultGenerator()
defaultTransition()
defaultInit(prob=c(0.2, 0.05, 0, 0.25, 0.5),
states=c("ReversePhasedFeature", "StableFeature",
"PhasedFeature", "NFRFeature", "FuzzyFeature"))
defaultLastFeat(isEnd = c(FALSE, rep(TRUE, 4)),
states=c("ReversePhasedFeature", "StableFeature",
"PhasedFeature", "NFRFeature", "FuzzyFeature"))
```

Arguments

- **prob**: Numeric vector giving the initial state distribution. This will be normalised if the probabilities do not add up to 1.
- **isEnd**: Logical vector indicating which states, i.e. features, are allowed to be last in the sequence.
- **states**: Character vector of state names.

Details

These functions generate data structures that can be passed as arguments to `makeFeatures`. Using this set of functions will create a nucleosome positioning simulation. Some of the defaults can be modified by passing different values to `defaultInit` and `defaultLastFeat`.

Value

Return values are suitable as arguments generator, transition, init and lastFeat of `makeFeatures`. See the documentation of `makeFeatures` for more detail.

Author(s)

Peter Humburg
Examples

```r
set.seed(1)
## generate defaults
generator <- defaultGenerator()
transition <- defaultTransition()
lastFeat <- defaultLastFeat()

## change the initial state distribution such that it
## always starts with a fuzzy feature
init <- defaultInit(c(0, 0, 0, 0, 1))

## now generate some features for a stretch of 1 million base pairs
features <- makeFeatures(generator=generator, transition=transition,
lastFeat=lastFeat, init=init, length=1e6)
```

---

**distDens**

*Computing densities for nucleosome positioning simulation*

**Description**

These functions compute nucleosome densities for a given parameter set (usually provided through one of the feature classes).

**Usage**

distDens(x, minDist = 175, varDist = 337.5, meanDist = 200)
fragDens(x, minLength, maxLength, meanLength, bind)
indNuc(meanDist = 200, length = 2000, weight = 1)
noNuc(length, weight = 1)
stableDens(x, shift = 10, ratio = 1, weight = 1, stability = 1)
phaseNuc(stable, dist, minDist = 175, length = 2000, meanDist = 200,
varDist = (meanDist - minDist) + (meanDist - minDist)^2/2,
shift = 10, ratio = 1, weight = 1, stability = 1)
bindLocDens(x, fragLength)

**Arguments**

- **x** Position at which the density should be evaluated.
- **minDist** Minimum distance between nucleosomes.
- **varDist** Variance of nucleosome distances.
- **meanDist** Mean distance of nucleosomes.
- **minLength** Minimum fragment length.
- **maxLength** Maximum fragment length.
- **meanLength** Mean fragment length.
- **bind** Position of binding site within fragment.
length  Length of region.
weight  Weight of feature.
stable  Density function for stable nucleosome.
dist    Density function of distances between nucleosomes.
shift   Distance between alternative position for stable nucleosome.
ratio   Ratio of probability mass associated with central and alternative positions for stable nucleosome.
stability Stability of stable nucleosome.
fragLength Length of DNA fragment. If x is not in [0, 1] this is used to normalize x.

Value
Density evaluated at the given position.

Author(s)
Peter Humburg

feat2dens

extractQuality

Description
Converts the read qualities encoded in fastq formatted files into error probabilities.

Usage
extractQuality(reads, minLength = 25, dir, 
type = c("Illumina", "Sanger", "Solexa"))

Arguments
reads  Either the name of a fastq file or a ShortReadQ object (see Details).
minLength Minimum read length required.
dir    Directory of fastq file.
type   Character string indicating the format the qualities are encoded in (see Details).
extractQuality

Details

If `reads` and `dir` are character strings it is assumed that `dir/reads` is the name of a fastq file. Otherwise `reads` should be a `ShortReadQ` object in which case `dir` is ignored.

Currently three different encodings of read qualities are supported. The encoding has to be selected via the `type` argument. The supported formats are

**Illumina** The format currently used by Illumina (version 1.3). This is a phred score between 0 and 40 encoded as ASCII characters 64 to 104. [default]

**Sanger** The Sanger format uses a phred quality score between 0 and 93 encoded as ASCII characters 33 to 126.

**Solexa** The old Solexa format previously used by Solexa/Illumina uses a quality score between -5 and 40 encoded as ASCII characters 59 to 104.

Value

A list with a vector of error probabilities for each read in `reads` that is at least `minLength` nucleotides long.

Author(s)

Peter Humburg

See Also

decodeQuality, readQualitySample

Examples

```r
## Not run:
## load reads from a fastq file with Sanger encoding
qualities <- extractQuality("test.fastq", dir=".", type="Sanger")

## extract error probabilities for first 25bp of each read
qualities25 <- sapply(qualities, "[", 1:25)

## plot average quality for each position
plot(rowMeans(qualities25), type='b', xlab="Read position", ylab="Error probability")

## End(Not run)
```
feat2dens

Convert a list of features into a feature density

Description

Given a list of features (as produced by `makeFeatures`) computes the feature density for each and combines them into a chromosome wide density.

Usage

```r
feat2dens(features, length, featureBgr = TRUE, ...)
```

Arguments

- `features`: A list of features.
- `length`: Total length of feature density vector (i.e. chromosome length). If this is missing the length is inferred from the feature parameters.
- `featureBgr`: Logical indicating whether feature specific background should be added to the density. If this is `TRUE` the resulting density for each feature is a mixture of the feature density and a fuzzy, i.e. uniform, feature density. The weights of the components are determined by the feature weight.
- `...`: Further arguments to `featureDensity`.

Value

A vector with the feature density for each position along the chromosome.

Author(s)

Peter Humburg

See Also

The majority of the work is done by calls to `featureDensity` and `joinRegion`.

Examples

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate density
featureDens <- feat2dens(features, length=1e5)
```
Description

This set of functions is used to generate the density of individual features of different types. `featureDensity` is an S3 generic, functions may be defined for different feature classes.

Usage

```r
featureDensity(x, ...)  
## S3 method for class 'StableFeature'
featureDensity(x, stable=stableDens, background=FALSE, ...)
## S3 method for class 'StablePhasedFeature'
featureDensity(x, stable=stableDens, dist=distDens, background=FALSE, ...)
## S3 method for class 'ReversePhasedFeature'
featureDensity(x, stable=stableDens, dist=distDens, background=FALSE, ...)
## S3 method for class 'NFRFeature'
featureDensity(x, background=FALSE, ...)
## S3 method for class 'FuzzyFeature'
featureDensity(x, ...)
```

Arguments

- `x` The feature for which the density should be computed.
- `stable` Function that should be used to compute the density of a stable feature.
- `dist` Function that should be used to compute the distribution of distances between adjacent features.
- `background` Logical indicating whether uniform background should be added to the feature.
- `...` Arguments to future functions.

Details

These functions are used internally by `feat2dens`. There should be no need to call them directly but it is important to supply suitable `featureDensity` functions for new feature types.

Value

A two column matrix. The first column contains the density, the second the weight at each position.

Author(s)

Peter Humburg

See Also

`feat2dens`, `makeFeatures`
## Examples

```r
## Create a single StableFeature
feature <- stableFeature(start = 200, weight = 0.8, shift = 10,
                          stability = 1, ratio = 1)

## Convert the feature into a density (without background)
featDens <- featureDensity(feature)

## If we want featureDensity to automatically add uniform background
## we have to ensure that the feature has a 'meanDist' parameter
## (this is usually added by 'reconcileFeatures').
feature$meanDist <- 200
featDens2 <- featureDensity(feature, background = TRUE)
```

---

### FeatureGenerators Generating Features

---

**Description**

These functions are used to generate the parameters for different nucleosome positioning related features.

**Usage**

```r
stableFeature(start, minDist = 175, weight = seq(0.1, 1, by = 0.1),
              shift = c(0, 5, 10), ratio = seq(0, 4, by = 0.25),
              stability = seq(0.1, 5, by = 0.1), weightProb, shiftProb,
              ratioProb, stabilityProb, ...)

phasedFeature(minDist = 175, length = seq(1000, 10000, by = minDist),
              meanDist = minDist:300, lengthProb, meanDistProb, start, ...)

fuzzyFeature(start, length = seq(1000, 10000, by = 1000),
             meanDist = 175:400, lengthProb, meanDistProb, ...

nfrFeature(start, length = seq(50, 500, by = 10),
           weight = seq(0.1, 1, by = 0.1), lengthProb, weightProb, ...
```

**Arguments**

- **start**  
  Start location of feature on chromosome.
- **minDist**  
  Minimum distance between nucleosomes.
- **length**  
  A numeric vector giving possible values for the length of the feature.
- **meanDist**  
  A numeric vector giving possible values for the mean distance between nucleosomes.
- **weight**  
  A numeric vector giving possible values for the weight of the feature.
- **shift**  
  A numeric vector giving possible values for the distance between favoured positions of stable nucleosomes.
These functions are only used internally or are lacking documentation.
joinRegion  

*Combining two feature densities*

**Description**

Function to take two vectors of feature densities and combine them into a single vector, using overlap between the two densities and smoothing the transition.

**Usage**

`joinRegion(left, right, overlap, overlapWeights)`

**Arguments**

- **left**: First density vector.
- **right**: Second density vector.
- **overlap**: Overlap between the two features.
- **overlapWeights**: Weights for overlapping region.

**Value**

Returns the combined density vector.

**Note**

This function is used as part of `feat2dens` and there should be no need to call it directly although it may be useful for possible extensions.

**Author(s)**

Peter Humburg

---

makeFeatures  

*Generating a list of genomic features*

**Description**

This function generates a list of genomic features for a single chromosome based on a Markov model.
makeFeatures

Usage

```r
makeFeatures(generator = defaultGenerator(),
transition = defaultTransition(), init = defaultInit(),
start = 1000, length, control = list(),
globals = list(minDist = 175), lastFeat = defaultLastFeat(),
experimentType = "NucleosomePosition",
truncate = FALSE, maxTries = 10, force=FALSE)
```

Arguments

- **generator**: A named list providing functions to generate the parameters associated with each type of feature. The name of each element in the list is the name of the state the function should be associated with.
- **transition**: Named list of transition probabilities. Each element is a (named) numeric vector giving the transition probabilities for the state indicated by the element’s name, i.e., each element of the list is a row of the transition probability matrix but zero probabilities can be omitted.
- **init**: Named numeric vector of initial state probabilities. The names have to correspond to state names of the model. Zero probabilities may be omitted.
- **start**: Numeric value indicating the position at which the first feature should be placed.
- **length**: Maximum length of DNA that should be covered with features.
- **control**: Named list with additional arguments to generator functions (one list per generator). Again the names should be the same as the state names.
- **globals**: List of global arguments to be passed to all generator functions.
- **lastFeat**: Named logical vector indicating for each feature type whether it can be the last feature.
- **experimentType**: Type of experiment the simulated features belong to. This is used as the class of the return value.
- **truncate**: Logical value indicating whether the final feature should be truncated to ensure that total length does not exceed `length` (if `FALSE`, a feature that would be truncated is removed instead).
- **maxTries**: Maximum number of attempts made to generate a valid sequence of features. If no valid sequence is generated during the first `maxTries` attempts the function will fail either silently (returning an empty sequence) or raise an error, depending on the value of `force`.
- **force**: Logical indicating whether the function should be forced to return a feature sequence, even if no valid sequence was found. If this is `TRUE` an empty sequence will be returned in that case otherwise an error is raised.

Details

This function will generate features from any first order Markov model specified by `init`, `transition` and `generator`. If `force` is `FALSE` the returned feature sequence is guaranteed to contain at least one feature and end in a state that is indicated as possible end state in `lastFeat`. Note that the states for which `lastFeat` is `TRUE` are not end states in the sense that the chain is terminated once the state
is entered or that the chain remains in the state once it is first entered. Instead this is a mechanism
to ensure that some states cannot be the last in the sequence.

Due to the constrains on the total length of DNA covered by features as well as the possible con-
straint on the final feature of the sequence it is possible to specify models that cannot produce a
legal sequence. In other cases it may be possible but unlikely to produce a feature sequence that
satisfies both constraints. A serious attempt is made to satisfy both requirement, generating a new
feature sequence or truncating an existing one if necessary. To ensure that this terminates eventually
the number of attempts to generate a valid sequence are limited to maxTries.

In some cases it may be desirable to carry out some post-processing of the feature sequence to
ensure that parameters of neighbouring features are compatible in some sense. For the default
nucleosome positioning simulation the function reconcileFeatures provides this functionality
and placeFeatures is an interface to makeFeatures that utilis reconcileFeatures.

Value

A list of features (with class determined by experimentType). Each feature is represented by a list
of parameters and has a class with the same name as the state that generated the feature. In addition
all features are of class SimulatedFeature.

Author(s)

Peter Humburg

See Also

Functions to generate default values for some of the arguments: defaultGenerator, defaultInit,
defaultTransition, defaultLastFeat.

Use feat2dens to convert a feature sequence into feature densities.

placeFeatures is an interface to makeFeature for nucleosome positioning.

Examples

set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- makeFeatures(length=1e6)

## check the total length of the features
sum(sapply(features, "[", "length")) # 995020

placeFeatures

Generating and reconciling a feature sequence

Description

This function provides an interface to makeFeatures and reconcileFeatures that combines both
steps of the feature generation process.
placeFeatures

Usage

placeFeatures(..., maxTail = 0.01,
compoundFeatures=list("StablePhasedFeature"))

Arguments

... Arguments to makeFeatures.
maxTail Maximum portion of total length of chromosome that may be left free of features (see Details).
compoundFeatures List of feature classes that are produced by combining two features. This may happen during the call to reconcileFeatures and requires special handling when extending the feature list.

Details

This function (as well as makeFeatures which it calls) tries to fill as much of the genomic region with features as possible, i.e. an attempt is made to produce a feature sequence that covers length base pairs. In most cases the sequence will be slightly shorter. The maxTail argument determines how long a region without any features at the end of the genomic region is acceptable (as fraction of the total length). Note however that even maxTail = 0 does not guarantee a feature sequence of exactly the requested length.

Value

A list of simulated features. The class of the return value as well as the features generated depend on the arguments passed to makeFeatures.

Note

Using the reconcileFeatures mechanism it is possible to introduce dependence between neighbouring features that is not easily expressed in terms of a simple Markov model. In some cases the same effect can be achieved by introducing additional states into the model but it may be more convenient to simply post-process the feature sequence.

Author(s)

Peter Humburg

See Also

makeFeatures, reconcileFeatures

Examples

set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(length=1e6, maxTail = 0)
## check the total length of the features

```r
sum(sapply(features, "[[", "length")) ## 990509
```

---

### pos2fastq

**Convert read positions to fastq records**

**Description**

Convert read positions for a single chromosome (both strands) into read sequences + qualities and write them to file.

**Usage**

```r
pos2fastq(readPos, names, quality, sequence, qualityFun, errorFun, readLen = 36, file, qualityType = c("Illumina", "Sanger", "Solexa"), ...)
```

**Arguments**

- `readPos` A list of two numeric vectors (one per strand).
- `names` List of names to use for reads in fastq file. Has to be of same shape as `name`.
- `quality` Passed on as argument to `qualityFun`.
- `sequence` Reference sequence (a DNAString object).
- `qualityFun` Function to generate quality scores.
- `errorFun` Function to introduce sequencing errors.
- `readLen` Read length to generate.
- `file` Output file (either file name or connection).
- `qualityType` Encoding to use for read quality scores.
- `...` Further arguments (see Details).

**Details**

Arguments passed as part of `...` will be passed on to `qualityFun`, except an argument called `prob` which is passed on to `errorFun` instead if present.

**Value**

Invisibly returns the number of records that were written.

**Author(s)**

Peter Humburg

**See Also**

See `readError` for a possible choice of `errorFun` and `readQualitySample` for a simple `qualityFun`. 
### Examples

```r
set.seed(1)

## a function to generate random read qualities (in Sanger format)
randomQuality <- function(read, ...){
paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),
length(read), replace = TRUE), collapse="")
}

## generate a reference sequence
chromosome <- DNAString(paste(sample(c("A", "C", "G", "T"),
1e5, replace = TRUE), collapse = ""))

## and a few read positions
reads <- list(sample(100:9900, 5), sample(100:9900, 5))
names <- list(paste("read", 1:5, sep="_"), paste("read", 6:10, sep="_"))

## convert to fastq format
pos2fastq(reads, names, sequence=chromosome, qualityFun=randomQuality,
errorFun=readError, file="")
```

---

### readError

**Introduce errors into read sequence based on quality scores**

#### Description

Given a read sequence and quality this function introduces errors by first choosing positions that should be modified based on the quality score and then exchanges nucleotides based on the probabilities given in `prob`.

#### Usage

```r
readError(read, qual, alphabet = c("A", "C", "G", "T"),
prob = defaultErrorProb(), ...)
```

#### Arguments

- `read`: A character string representing a read sequence.
- `qual`: Numeric vector of read error probabilities.
- `alphabet`: Alphabet used for read sequence.
- `prob`: Nucleotide exchange probabilities.
- `...`: Further arguments (currently ignored).

#### Details

If the read sequence contains letters that are not part of `alphabet` they are replaced by the first entry of `alphabet` before positions of sequencing errors are determined. The alphabet used has to match the names used in `prob`. 
Value

The modified read sequence.

Author(s)

Peter Humburg

See Also

defaultErrorProb, readSequence

Examples

set.seed(42)

## generate sequence read and quality
quality <- paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),
36, replace = TRUE), collapse="")
errorProb <- decodeQuality(quality, type = "Sanger")
read <- paste(sample(c("A", "C", "G", "T"), 36, replace = TRUE),
collapse = "")

## use readError to introduce sequencing errors
read2 <- readError(read, errorProb)

all.equal(read, read2)  ## "1 string mismatch"

---

readQualitySample  Sample read qualities from a list

Description

Given a read sequence and a list of read quality scores this function returns a (possibly truncated) quality score of the same length as the read.

Usage

readQualitySample(read, qualities, checkLength = TRUE, ...)

Arguments

read  A sequence read.
qualities  List of sequence read quality scores.
checkLength  Flag indicating whether the length of quality scores should be checked to ensure that they are at least as long as the read. If qualities contains entries shorter than read this has to be TRUE, but see below.
...  Further arguments, currently not used.
Details

Using `checkLength = TRUE` leads to a substantial decrease in performance and is impractical for a large simulation. To avoid this slow down it is recommended to remove short sequences from qualities beforehand so that `checkLength = FALSE` can be used.

Value

An read quality score string of the same length as `read`.

Author(s)

Peter Humburg

---

**readSequence**  
*Convert read position into read sequence*

Description

Given a read position, a reference sequence, a strand and a read length this function returns the read sequence.

Usage

```r
readSequence(readPos, sequence, strand, readLen = 36)
```

Arguments

- `readPos` Numeric value indicating the start position on the chromosome.
- `sequence` Chromosome sequence ([DNAString])
- `strand` Strand indicator (+1 / -1)
- `readLen` Length of read.

Value

Read sequence.

Author(s)

Peter Humburg

See Also

`readError`, `writeReads`
reconcileFeatures  

Post-processing of simulated features

Description

The `reconcileFeatures` functions provide a facility to post-process a list of features representing a simulated experiment. `reconcileFeatures` is an S3 generic, new functions can be added for additional types of experiment. The current default is to call `reconcileFeatures.SimulatedExperiment` which, if called without further arguments, will simply return the feature list unchanged.

Usage

```r
reconcileFeatures(features, ...)  
## Default S3 method:  
reconcileFeatures(features, ...)  
## S3 method for class 'SimulatedExperiment'  
reconcileFeatures(features, defaultValues = list(), ...)  
## S3 method for class 'NucleosomePosition'  
reconcileFeatures(features, defaultMeanDist = 200, ...)  
```

Arguments

- `features`: List of simulated features.
- `defaultValues`: Named list of default parameter values. The method for class `SimulatedExperiment` ensures that all features have at least the parameters listed in `defaultValues`, adding them where necessary.
- `defaultMeanDist`: Default value for the average distance between nucleosomes for nucleosome positioning experiments.
- `...`: Further arguments to future functions.

Value

A list of features of the same class as `features`.

sampleReads

Sampling sequence read positions from a read density.

Description

Given a read density this function returns the starting positions of sequence reads.

Usage

sampleReads(readDens, nreads = 6e+06, strandProb = c(0.5, 0.5))

Arguments

readDens A two column matrix of read densities (as produced by bindDens2readDens).
nreads Number of read positions to generate.
strandProb A numeric vector with two elements giving weights for forward and reverse strand.

Details

The expected number of reads for each strand is strandProb * nreads.

Value

A list with components fwd and rev giving the read positions on the forward and reverse strand respectively.

Author(s)

Peter Humburg
See Also

bindDens2readDens

Examples

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate feature density
featureDens <- feat2dens(features, length=1e5)

## convert to read density
readDens <- bindDens2readDens(featureDens, fragDens, meanLength=160)

## sample reads
## of course you would usually want a much larger number
readPos <- sampleReads(readDens, nreads=1000)
```

simChIP

Simulate ChIP-seq experiments

Description

This function acts as driver for the simulation. It takes all required arguments and passes them on to the functions for the different stages of the simulation. The current defaults will simulate a nucleosome positioning experiment.

Usage

`simChIP(nreads, genome, file, functions = defaultFunctions(), control = defaultControl(), verbose = TRUE, load = FALSE)`

Arguments

- `nreads`: Number of reads to generate.
- `genome`: An object of class 'DNAStringSet' or the name of a fasta file containing the genome sequence.
- `file`: Base of output file names (see Details).
- `control`: Named list of arguments to be passed to simulation functions (one list per function).
- `verbose`: Logical indicating whether progress messages should be printed.
- `load`: Logical indicating whether an attempt should be made to load intermediate results from a previous run.
Details

The simulation consists of six stages:

1. generate feature sequence (for each chromosome): chromosome length -> feature sequence (list)
2. compute binding site density: feature sequence -> binding site density (vector)
3. compute read density: binding site density -> read density (two column matrix, one column for each strand)
4. sample read start sites: read density -> read positions (list)
5. create read names: number of reads -> unique names
6. obtain read sequence and quality: read positions, genome sequence, [qualities] -> output file

After each of the first three stages the results of the stage are written to a file and can be reused later. File names are created by appending '_features.rdata', '_bindDensity.rdata' and '_readDensity.rdata' to file respectively. Previous results will be loaded for reuse if load is TRUE and files with matching names are found. This is useful to sample repeatedly from the same read density or to recover partial results from an interrupted run.

The creation of files can be prevented by setting file = "". In this case all results will be returned in a list at the end. Note that this will require more memory since all intermediate results have to be held until the end.

The behaviour of the simulation is mainly controlled through the functions and control arguments. They are expected to be lists of the same length with matching names. The names indicate the stage of the simulation for which the function should be used; elements of control will be used as arguments for the corresponding functions.

Value

A list. The components are typically either lists (with one component per chromosome) or file names but note that this may depend on the return value of functions listed in functions. The components of the returned list are:

- **features**: Either a list of generated features or the name of a file containing that list;
- **bindDensity**: Either a list with binding site densities or the name of a file containing that list;
- **readDensity**: Either a list of read densities or the name of a file containing that list;
- **readPosition**: Either a list of read start sites or the name of a file containing that list;
- **readSequence**: The return value of the function listed as 'readSequence'. The default for this the name of the fastq file containing the read sequences;
- **readNames**: Either a list of read names or the name of a file containing that list.

defaultFunctions, defaultControl
simpleNames

Generate unique read names

Description

Generates a set of unique (and very simple) read names.

Usage

```
simpleNames(n, nameBase = "read")
```

Arguments

- `n` Number of names to generate.
- `nameBase` Base name to use.

Value

A character vector with entries of the form ‘nameBase_i’ where i runs from 1 to n.

Author(s)

Peter Humburg

Examples

```
simpleNames(5)
```
Write read sequences and qualities to a FASTQ formatted file

Description

This is intended to produce the final output of the simulation by providing a fastq file that may then be used in an analysis pipeline.

Usage

writeFASTQ(read, quality, name, file, append = FALSE)

Arguments

- **read**: List of read sequences.
- **quality**: List of read quality scores.
- **name**: Read names.
- **file**: File name. If this is "" results will be printed to the standard output connection.
- **append**: Logical indicating the reads should be appended to an existing file.

Details

The first three arguments should have the same length but will be recycled if necessary.

Value

Called for its side effect.

readSequence, readQualitySample, writeReads

Examples

```r
set.seed(1)

## generate sequence read and quality
quality <- paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),36, replace = TRUE), collapse="")
read <- paste(sample(c("A", "C", "G", "T"), 36, replace = TRUE), collapse = "")

## write a fastq record
writeFASTQ(read, quality, "read_1", file="")
```
writeReads

Create fastq file from read positions

**Description**
This is an interface to `pos2fastq` that writes all reads for a given genome to a single file.

**Usage**

```
writeReads(readPos, readNames, sequence, quality, file, ...)
```

**Arguments**

- `readPos`: List of read positions with each component holding the read positions for one chromosome, which are themselves two component lists that provide forward and reverse strand positions.
- `readNames`: List of the same shape as `readPos` providing read names.
- `sequence`: Genome reference sequence (a `DNAStringSet`).
- `quality`: Read quality scores (see Details).
- `file`: Output file.
- `...`: Further arguments to `pos2fastq`.

**Details**
If `quality` looks like it might refer to a fastq file an attempt is made to create a `ShortReadQ` object. The read qualities of any `ShortReadQ` object passed as `quality` (directly or indirectly as file name) are extracted and passed on to `pos2fastq` as `quality` argument. Otherwise it is passed on unchanged.

**Value**
The name of the output file.
