Package ‘ChIPsim’

February 20, 2024

Type Package
Title Simulation of ChIP-seq experiments
Version 1.56.0
Date 2011-05-18
Author Peter Humburg
Maintainer Peter Humburg <Peter.Humburg@gmail.com>
Description A general framework for the simulation of ChIP-seq data. Although currently focused on nucleosome positioning the package is designed to support different types of experiments.
License GPL (>= 2)
LazyLoad yes
Depends Biostrings (>= 2.29.2)
Imports IRanges, XVector, Biostrings, ShortRead, graphics, methods, stats, utils
Suggests actuar, zoo
biocViews Infrastructure, ChIPSeq
git_url https://git.bioconductor.org/packages/ChIPsim
git_branch RELEASE_3_18

ChIPsim-package

Simulation of ChIP-seq experiments

Description

This package provides a framework for the simulation of ChIP-seq experiments. An implementation of a simulation for nucleosome positioning experiments is provided as part of the package. Simulations for other experiments can be implemented using the provided framework.

Details

Package: ChIPsim
Type: Package
Version: 1.3.1
Date: 2010-07-30
License: GPL (>= 2)
LazyLoad: yes
Depends: Biostrings
Imports: IRanges, ShortRead
Suggests: actuar, zoo
Function `simChIP` is the main driver of the simulation. To simulate different types of experiments the functions passed to the `functions` argument of `simChIP` have to be replaced. See the vignettes for more detail.

**Author(s)**

Peter Humburg

Maintainer: Peter Humburg <Peter.Humburg@well.ox.ac.uk>

**References**

~~ Literature or other references for background information ~~

**See Also**

`ShortRead` and its dependencies are used to handle short read and genomic sequences.

**Examples**

```r
## See the accompanying vignette 'Introduction to ChIPsim' for a detailed
## example of how to use this package for nucleosome positioning simulations.
## A guide for the writing of extensions that cover other types of
## experiments is provided in 'Extending ChIPsim'.
```

---

`bindDens2readDens`  
*Convert a feature density into a read density*

**Description**

Given a feature density this function produces two read densities, one for each strand.

**Usage**

```r
bindDens2readDens(bindDens, fragment, nfrag = 1e+05, bind = 147,
            minLength = 150, maxLength = 180, ...)
```

**Arguments**

- `bindDens`: Numeric vector with the feature density for one chromosome.
- `fragment`: Function giving the fragment length distribution.
- `nfrag`: Number of fragments that should be simulated to generate the read distribution.
- `bind`: Length of binding site.
- `minLength`: Minimum fragment length.
- `maxLength`: Maximum fragment length.
- `...`: Further arguments to `fragment`.
decodeQuality

Value

A two column matrix. The first column contains the read density for the forward strand, the second column the read density for the reverse strand.

Author(s)

Peter Humburg

See Also

feat2dens, sampleReads

Examples

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate feature density
featureDens <- feat2dens(features, length=1e5)

## convert to read density
readDens <- bindDens2readDens(featureDens, fragDens, meanLength=160)
```

decodeQuality

Conversion between numerical and ASCII representation of read qualities

Description

These functions convert an ASCII encoded sequence of read qualities into a numeric vector of error probabilities and vice versa.

Usage

```r
decodeQuality(quality, type = c("Illumina", "Sanger", "Solexa"))
encodeQuality(quality, type = c("Illumina", "Sanger", "Solexa"))
```

Arguments

- **quality**: For decodeQuality a character string representing the read qualities for a single sequence read. For encodeQuality a numeric vector of error probabilities.
- **type**: Type of encoding to use.

Details

See `extractQuality` for a description of the currently supported encodings.
Value

Either a numeric vector of error probabilities or a character string of encoded read quality scores. Each entry in the vector corresponds to one character in the input.

Author(s)

Peter Humburg

See Also

extractQuality

Examples

## decodeQuality and encodeQuality are the inverse operations
## of each other as one might expect
quality <- "IIIIIIIIIIIIICIIIG1II95III6II-II0"
errorProb <- decodeQuality(quality, type="Sanger")
qualitySanger <- encodeQuality(errorProb, type="Sanger")
all.equal(quality, qualitySanger)

## They can also be used to convert between encodings
qualityIllumina <- encodeQuality(errorProb, type="Illumina")

defaultControl

Default parameters for simChIP

Description

Produces a list of parameters for each of the functions used to carry out the various stages of the simulation.

Usage

defaultControl(features = list(), bindDensity = list(),
readDensity = list(), readNames = list(), readSequence = list())

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>features</td>
<td>Parameters for feature generation.</td>
</tr>
<tr>
<td>bindDensity</td>
<td>Parameters for the conversion of feature sequence into binding site densities.</td>
</tr>
<tr>
<td>readDensity</td>
<td>Parameters for the conversion of binding site densities into read densities.</td>
</tr>
<tr>
<td>readNames</td>
<td>Parameters for the generation of read names.</td>
</tr>
<tr>
<td>fragment</td>
<td>Default: <strong>fragDens</strong></td>
</tr>
<tr>
<td>meanLength</td>
<td>Default: 160</td>
</tr>
</tbody>
</table>

extractQuality
readSequence

Parameters for the conversion of read positions into read sequences. Always provides parameters

- qualityFun: readQualitySample
- errorFun: readError
- readLen: 36

Details

Any parameters passed as part of list to one of the arguments of defaultControl will be passed on to the corresponding function in simChIP. The build-in defaults can be overwritten by providing a list entry with the same name.

Value

List of parameters for use as the control argument to simChIP.

Author(s)

Peter Humburg

See Also

defaultFunctions, simChIP

Examples

defaultControl()
defaultControl(features=list(maxTail=0), readSequence=list(readLen=50))

defaultErrorProb

Replacement probabilities for sequencing errors

Description

For each nucleotide this function provides probabilities indicating how likely it is to be replaced by any of the other nucleotides should a sequencing error occur.

Usage

defaultErrorProb()

Details

The probabilities used here are the ones determined by Dohm et al. for Beta vulgaris. They should be more appropriate than a uniform distribution but the use of species specific rates is recommended where available.
**Value**

A list of four vectors with replacement probabilities for each nucleotide.

**Author(s)**

Peter Humburg

**References**

**Examples**

```r
defaultErrorProb()
```

---

**Description**

Provides default functions to carry out the different stages of the ChIP-seq simulation.

**Usage**

```r
defaultFunctions()
```

**Value**

A list with components

- `features`: *placeFeatures*
- `bindDensity`: *feat2dens*
- `readDensity`: *bindDens2readDens*
- `sampleReads`: *sampleReads*
- `readSequence`: *writeReads*
- `readNames`: *simpleNames*

**Author(s)**

Peter Humburg

**See Also**

`simChIP`
**Examples**

defaultFunctions()

defaultGenerator()  Defaults for Feature Generator

**Description**

Functions to generate defaults for `makeFeatures`.

**Usage**

defaultGenerator()
defaultTransition()defaultInit(prob=c(0.2, 0.05, 0, 0.25, 0.5), states=c("ReversePhasedFeature", "StableFeature", "PhasedFeature", "NFRFeature", "FuzzyFeature"))defaultLastFeat(isEnd = c(FALSE, rep(TRUE, 4)), states = c("ReversePhasedFeature", "StableFeature", "PhasedFeature", "NFRFeature", "FuzzyFeature"))

**Arguments**

- **prob**: Numeric vector giving the initial state distribution. This will be normalised if the probabilities do not add up to 1.
- **isEnd**: Logical vector indicating which states, i.e. features, are allowed to be last in the sequence.
- **states**: Character vector of state names.

**Details**

These functions generate data structures that can be passed as arguments to `makeFeatures`. Using this set of functions will create a nucleosome positioning simulation. Some of the defaults can be modified by passing different values to `defaultInit` and `defaultLastFeat`.

**Value**

Return values are suitable as arguments `generator`, `transition`, `init` and `lastFeat` of `makeFeatures`. See the documentation of `makeFeatures` for more detail.

**Author(s)**

Peter Humburg
Examples

```
set.seed(1)
## generate defaults
generator <- defaultGenerator()
transition <- defaultTransition()
lastFeat <- defaultLastFeat()

## change the initial state distribution such that it
## always starts with a fuzzy feature
init <- defaultInit(c(0, 0, 0, 0, 1))

## now generate some features for a stretch of 1 million base pairs
features <- makeFeatures(generator=generator, transition=transition,
lastFeat=lastFeat, init=init, length=1e6)
```

---

**distDens**

*Computing densities for nucleosome positioning simulation*

**Description**

These functions compute nucleosome densities for a given parameter set (usually provided through one of the feature classes).

**Usage**

```
distDens(x, minDist = 175, varDist = 337.5, meanDist = 200)
fragDens(x, minLength, maxLength, meanLength, bind)
indNuc(meanDist = 200, length = 2000, weight = 1)
noNuc(length, weight = 1)
stableDens(x, shift = 10, ratio = 1, weight = 1, stability = 1)
phaseNuc(stable, dist, minDist = 175, length = 2000, meanDist = 200,
varDist = (meanDist - minDist) + (meanDist - minDist)^2/2,
shift = 10, ratio = 1, weight = 1, stability = 1)
bindLocDens(x, fragLength)
```

**Arguments**

- `x` - Position at which the density should be evaluated.
- `minDist` - Minimum distance between nucleosomes.
- `varDist` - Variance of nucleosome distances.
- `meanDist` - Mean distance of nucleosomes.
- `minLength` - Minimum fragment length.
- `maxLength` - Maximum fragment length.
- `meanLength` - Mean fragment length.
- `bind` - Position of binding site within fragment.
length        Length of region.
weight        Weight of feature.
stable        Density function for stable nucleosome.
dist          Density function of distances between nucleosomes.
shift         Distance between alternative position for stable nucleosome.
ratio         Ratio of probability mass associated with central and alternative positions for
              stable nucleosome.
stability      Stability of stable nucleosome.
fragLength     Length of DNA fragment. If x is not in [0, 1] this is used to normalize x.

Value
Density evaluated at the given position.

Author(s)
Peter Humburg

feat2dens

---

**extractQuality**

*Obtain read qualities from a Fastq file or ShortReadQ object*

**Description**
Converts the read qualities encoded in fastq formatted files into error probabilities.

**Usage**

```r
extractQuality(reads, minLength = 25, dir,
               type = c("Illumina", "Sanger", "Solexa"))
```

**Arguments**
- **reads**  Either the name of a fastq file or a ShortReadQ object (see Details).
- **minLength**  Minimum read length required.
- **dir**  Directory of fastq file.
- **type**  Character string indicating the format the qualities are encoded in (see Details).
extractQuality

Details

If `reads` and `dir` are character strings it is assumed that `dir/reads` is the name of a fastq file. Otherwise `reads` should be a `ShortReadQ` object in which case `dir` is ignored.

Currently three different encodings of read qualities are supported. The encoding has to be selected via the `type` argument. The supported formats are

**Illumina** The format currently used by Illumina (version 1.3). This is a phred score between 0 and 40 encoded as ASCII characters 64 to 104. [default]

**Sanger** The Sanger format uses a phred quality score between 0 and 93 encoded as ASCII characters 33 to 126.

**Solexa** The old Solexa format previously used by Solexa/Illumina uses a quality score between -5 and 40 encoded as ASCII characters 59 to 104.

Value

A list with a vector of error probabilities for each read in `reads` that is at least `minLength` nucleotides long.

Author(s)

Peter Humburg

See Also

decodeQuality, readQualitySample

Examples

```r
## Not run:
## load reads from a fastq file with Sanger encoding
qualities <- extractQuality("test.fastq", dir=".", type="Sanger")

## extract error probabilities for first 25bp of each read
qualities25 <- sapply(qualities, "[", 1:25)

## plot average quality for each position
plot(rowMeans(qualities25), type='b', xlab="Read position", ylab="Error probability")

## End(Not run)
```
feat2dens  

_Convert a list of features into a feature density_

**Description**

Given a list of features (as produced by `makeFeatures`) computes the feature density for each and combines them into a chromosome wide density.

**Usage**

```r
defeat2dens(features, length, featureBgr = TRUE, ...)
```

**Arguments**

- `features`: A list of features.
- `length`: Total length of feature density vector (i.e. chromosome length). If this is missing the length is inferred from the feature parameters.
- `featureBgr`: Logical indicating whether feature specific background should be added to the density. If this is `TRUE` the resulting density for each feature is a mixture of the feature density and a fuzzy, i.e. uniform, feature density. The weights of the components are determined by the feature weight.
- `...`: Further arguments to `featureDensity`.

**Value**

A vector with the feature density for each position along the chromosome.

**Author(s)**

Peter Humburg

**See Also**

The majority of the work is done by calls to `featureDensity` and `joinRegion`.

**Examples**

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate density
featureDens <- feat2dens(features, length=1e5)
```
**Description**

This set of functions is used to generate the density of individual features of different types. `featureDensity` is an S3 generic, functions may be defined for different feature classes.

**Usage**

```r
featureDensity(x, ...)  
## S3 method for class 'StableFeature'
featureDensity(x, stable=stableDens, background=FALSE, ...)
## S3 method for class 'StablePhasedFeature'
featureDensity(x, stable=stableDens, dist=distDens, background=FALSE, ...)
## S3 method for class 'ReversePhasedFeature'
featureDensity(x, stable=stableDens, dist=distDens, background=FALSE, ...)
## S3 method for class 'NFRFeature'
featureDensity(x, background=FALSE, ...)
## S3 method for class 'FuzzyFeature'
featureDensity(x, ...)
```

**Arguments**

- `x` The feature for which the density should be computed.
- `stable` Function that should be used to compute the density of a stable feature.
- `dist` Function that should be used to compute the distribution of distances between adjacent features.
- `background` Logical indicating whether uniform background should be added to the feature.
- `...` Arguments to future functions.

**Details**

These functions are used internally by `feat2dens`. There should be no need to call them directly but it is important to supply suitable `featureDensity` functions for new feature types.

**Value**

A two column matrix. The first column contains the density, the second the weight at each position.

**Author(s)**

Peter Humburg

**See Also**

`feat2dens`, `makeFeatures`
Examples

```r
## Create a single StableFeature
feature <- stableFeature(start = 200, weight = 0.8, shift = 10,
stability = 1, ratio = 1)

## Convert the feature into a density (without background)
featDens <- featureDensity(feature)

## If we want featureDensity to automatically add uniform background
## we have to ensure that the feature has a 'meanDist' parameter
## (this is usually added by 'reconcileFeatures').
feature$meanDist <- 200
featDens2 <- featureDensity(feature, background = TRUE)
```

---

### FeatureGenerators  Generating Features

**Description**

These functions are used to generate the parameters for different nucleosome positioning related features.

**Usage**

```r
stableFeature(start, minDist = 175, weight = seq(0.1, 1, by = 0.1),
shift = c(0, 5, 10), ratio = seq(0, 4, by = 0.25),
stability = seq(0.1, 5, by = 0.1), weightProb, shiftProb,
ratioProb, stabilityProb, ...)
phasedFeature(minDist = 175, length = seq(1000, 10000, by = minDist),
meanDist = minDist:300, lengthProb, meanDistProb, start, ...)
fuzzyFeature(start, length = seq(1000, 10000, by = 1000),
meanDist = 175:400, lengthProb, meanDistProb, ...)
nfrFeature(start, length = seq(50, 500, by = 10),
weight = seq(0.1, 1, by = 0.1), lengthProb, weightProb, ...)
```

**Arguments**

- `start`  Start location of feature on chromosome.
- `minDist`  Minimum distance between nucleosomes.
- `length`  A numeric vector giving possible values for the length of the feature.
- `meanDist`  A numeric vector giving possible values for the mean distance between nucleosomes.
- `weight`  A numeric vector giving possible values for the weight of the feature.
- `shift`  A numeric vector giving possible values for the distance between favoured positions of stable nucleosomes.
ratio  A numeric vector giving possible values for the ratio between probabilities for alternative and central position of stable nucleosomes.

stability A numeric vector giving possible values for the stability of stable nucleosomes.

lengthProb Length distribution of feature. This corresponds to the state duration distribution of the underlying generating model.

meanDistProb Distribution of mean distances between nucleosomes.

weightProb Distribution of feature weights.

shiftProb Distribution of distances between favoured positions of stable nucleosome.

ratioProb Ratio distribution.

stabilityProb Stability distribution.

... Further arguments (currently ignored).

Value

A list of parameters for the corresponding feature type. These parameters are later used to compute nucleosome densities.

Author(s)

Peter Humburg

simChIP

Examples

feature <- stableFeature(200)
joinRegion

Combining two feature densities

Description

Function to take two vectors of feature densities and combine them into a single vector, using overlap between the two densities and smoothing the transition.

Usage

joinRegion(left, right, overlap, overlapWeights)

Arguments

- **left**: First density vector.
- **right**: Second density vector.
- **overlap**: Overlap between the two features.
- **overlapWeights**: Weights for overlapping region.

Value

Returns the combined density vector.

Note

This function is used as part of feat2dens and there should be no need to call it directly although it may be useful for possible extensions.

Author(s)

Peter Humburg

makeFeatures

Generating a list of genomic features

Description

This function generates a list of genomic features for a single chromosome based on a Markov model.
Usage

makeFeatures(generator = defaultGenerator(),
transition = defaultTransition(), init = defaultInit(),
start = 1000, length, control = list(),
globals = list(minDist = 175), lastFeat = defaultLastFeat(),
experimentType = "NucleosomePosition",
truncate = FALSE, maxTries = 10, force=FALSE)

Arguments

generator  A named list providing functions to generate the parameters associated with each type of feature. The name of each element in the list is the name of the state the function should be associated with.

transition  Named list of transition probabilities. Each element is a (named) numeric vector giving the transition probabilities for the state indicated by the element’s name, i.e., each element of the list is a row of the transition probability matrix but zero probabilities can be omitted.

init  Named numeric vector of initial state probabilities. The names have to correspond to state names of the model. Zero probabilities may be omitted.

start  Numeric value indicating the position at which the first feature should be placed.

length  Maximum length of DNA that should be covered with features.

control  Named list with additional arguments to generator functions (one list per generator). Again the names should be the same as the state names.

globals  List of global arguments to be passed to all generator functions.

lastFeat  Named logical vector indicating for each feature type whether it can be the last feature.

experimentType  Type of experiment the simulated features belong to. This is used as the class of the return value.

truncate  Logical value indicating whether the final feature should be truncated to ensure that total length does not exceed length (if FALSE, a feature that would be truncated is removed instead).

maxTries  Maximum number of attempts made to generate a valid sequence of features. If no valid sequence is generated during the first maxTries attempts the function will fail either silently (returning an empty sequence) or raise an error, depending on the value of force.

force  Logical indicating whether the function should be forced to return a feature sequence, even if no valid sequence was found. If this is TRUE an empty sequence will be returned in that case otherwise an error is raised.

Details

This function will generate features from any first order Markov model specified by init, transition and generator. If force is FALSE the returned feature sequence is guaranteed to contain at least one feature and end in a state that is indicated as possible end state in lastFeat. Note that the states for which lastFeat is TRUE are not end states in the sense that the chain is terminated once the state
is entered or that the chain remains in the state once it is first entered. Instead this is a mechanism to ensure that some states cannot be the last in the sequence.

Due to the constrains on the total length of DNA covered by features as well as the possible constraint on the final feature of the sequence it is possible to specify models that cannot produce a legal sequence. In other cases it may be possible but unlikely to produce a feature sequence that satisfies both constraints. A serious attempt is made to satisfy both requirement, generating a new feature sequence or truncating an existing one if necessary. To ensure that this terminates eventually the number of attempts to generate a valid sequence are limited to \texttt{maxTries}.

In some cases it may be desirable to carry out some post-processing of the feature sequence to ensure that parameters of neighbouring features are compatible in some sense. For the default nucleosome positioning simulation the function \texttt{reconcileFeatures} provides this functionality and \texttt{placeFeatures} is an interface to \texttt{makeFeatures} that utilises \texttt{reconcileFeatures}.

\section*{Value}

A list of features (with class determined by \texttt{experimentType}). Each feature is represented by a list of parameters and has a class with the same name as the state that generated the feature. In addition all features are of class \texttt{SimulatedFeature}.

\section*{Author(s)}

Peter Humburg

\section*{See Also}

Functions to generate default values for some of the arguments: \texttt{defaultGenerator, defaultInit, defaultTransition, defaultLastFeat}. Use \texttt{feat2dens} to convert a feature sequence into feature densities. \texttt{placeFeatures} is an interface to \texttt{makeFeature} for nucleosome positioning.

\section*{Examples}

\begin{verbatim}
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- makeFeatures(length=1e6)

## check the total length of the features
sum(sapply(features, '[', 'length')) # 995020
\end{verbatim}

---

\section*{placeFeatures} \hspace{1cm} \textit{Generating and reconciling a feature sequence}

\section*{Description}

This function provides an interface to \texttt{makeFeatures} and \texttt{reconcileFeatures} that combines both steps of the feature generation process.
placeFeatures

Usage

placeFeatures(..., maxTail = 0.01,
compoundFeatures=list("StablePhasedFeature"))

Arguments

... Arguments to makeFeatures.
maxTail Maximum portion of total length of chromosome that may be left free of features (see Details).
compoundFeatures List of feature classes that are produced by combining two features. This may happen during the call to reconcileFeatures and requires special handling when extending the feature list.

Details

This function (as well as makeFeatures which it calls) tries to fill as much of the genomic region with features as possible, i.e. an attempt is made to produce a feature sequence that covers length base pairs. In most cases the sequence will be slightly shorter. The maxTail argument determines how long a region without any features at the end of the genomic region is acceptable (as fraction of the total length). Note however that even maxTail = 0 does not guarantee a feature sequence of exactly the requested length.

Value

A list of simulated features. The class of the return value as well as the features generated depend on the arguments passed to makeFeatures.

Note

Using the reconcileFeatures mechanism it is possible to introduce dependence between neighbouring features that is not easily expressed in terms of a simple Markov model. In some cases the same effect can be achieved by introducing additional states into the model but it may be more convenient to simply post-process the feature sequence.

Peter Humburg

See Also

makeFeatures, reconcileFeatures

Examples

set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(length=1e6, maxTail = 0)
## check the total length of the features
```
sum(sapply(features, "[[", "length"))  # 990509
```

---

**pos2fastq**  
*Convert read positions to fastq records*

**Description**
Convert read positions for a single chromosome (both strands) into read sequences + qualities and write them to file

**Usage**
```
pos2fastq(readPos, names, quality, sequence, qualityFun, errorFun,  
readLen = 36, file,  
qualityType = c("Illumina", "Sanger", "Solexa"), ...)
```

**Arguments**
- `readPos` A list of two numeric vectors (one per strand)
- `names` List of names to use for reads in fastq file. Has to be of same shape as name.
- `quality` Passed on as argument to `qualityFun`
- `sequence` Reference sequence (a `DNASTing` object)
- `qualityFun` Function to generate quality scores
- `errorFun` Function to introduce sequencing errors.
- `readLen` Read length to generate.
- `file` Output file (either file name or connection).
- `qualityType` Encoding to use for read quality scores.
- `...` Further arguments (see Details).

**Details**
Arguments passed as part of ... will be passed on to `qualityFun`, except an argument called `prob` which is passed on to `errorFun` instead if present.

**Value**
Invisibly returns the number of records that were written.

**Author(s)**
Peter Humburg

**See Also**
See `readError` for a possible choice of `errorFun` and `readQualitySample` for a simple `qualityFun`.
**Examples**

```r
set.seed(1)

## a function to generate random read qualities (in Sanger format)
randomQuality <- function(read, ...){
paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),
       length(read), replace = TRUE), collapse="")
}

## generate a reference sequence
chromosome <- DNAString(paste(sample(c("A", "C", "G", "T"),
       1e5, replace = TRUE), collapse = ""))

## and a few read positions
reads <- list(sample(100:9900, 5), sample(100:9900, 5))
names <- list(paste("read", 1:5, sep="_"), paste("read", 6:10, sep="_"))

## convert to fastq format
pos2fastq(reads, names, sequence=chromosome, qualityFun=randomQuality,
          errorFun=readError, file="")
```

---

**readError**

*Introduce errors into read sequence based on quality scores*

**Description**

Given a read sequence and quality this function introduces errors by first choosing positions that should be modified based on the quality score and then exchanges nucleotides based on the probabilities given in `prob`.

**Usage**

```r
readError(read, qual, alphabet = c("A", "C", "G", "T"),
          prob = defaultErrorProb(), ...)
```

**Arguments**

- `read` A character string representing a read sequence.
- `qual` Numeric vector of read error probabilities.
- `alphabet` Alphabet used for read sequence.
- `prob` Nucleotide exchange probabilities.
- `...` Further arguments (currently ignored).

**Details**

If the read sequence contains letters that are not part of `alphabet` they are replaced by the first entry of `alphabet` before positions of sequencing errors are determined. The alphabet used has to match the names used in `prob`. 
Value

The modified read sequence.

Author(s)

Peter Humburg

defaultErrorProb, readSequence

Examples

set.seed(42)

## generate sequence read and quality
quality <- paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),
36, replace = TRUE), collapse="")
errorProb <- decodeQuality(quality, type = "Sanger")
read <- paste(sample(c("A", "C", "G", "T"), 36, replace = TRUE),
collapse = "")

## use readError to introduce sequencing errors
read2 <- readError(read, errorProb)

all.equal(read, read2)  ## "1 string mismatch"

---

**readQualitySample**  
*Sample read qualities from a list*

Description

Given a read sequence and a list of read quality scores this function returns a (possibly truncated) quality score of the same length as the read.

Usage

readQualitySample(read, qualities, checkLength = TRUE, ...)

Arguments

- **read**: A sequence read.
- **qualities**: List of sequence read quality scores.
- **checkLength**: Flag indicating whether the length of quality scores should be checked to ensure that they are at least as long as the read. If qualities contains entries shorter than read this has to be TRUE, but see below.
- **...**: Further arguments, currently not used.
Details
Using checkLength = TRUE leads to a substantial decrease in performance and is impractical for a large simulation. To avoid this slow down it is recommended to remove short sequences from qualities beforehand so that checkLength = FALSE can be used.

Value
An read quality score string of the same length as read.

Author(s)
Peter Humburg

---

**readSequence**

*Convert read position into read sequence*

Description
Given a read position, a reference sequence, a strand and a read length this function returns the read sequence.

Usage
```
readSequence(readPos, sequence, strand, readLen = 36)
```

Arguments
- **readPos** Numeric value indicating the start position on the chromosome.
- **sequence** Chromosome sequence (a DNAString)
- **strand** Strand indicator (+1 / -1)
- **readLen** Length of read.

Value
Read sequence.

readError, writeReads
reconcileFeatures  Post-processing of simulated features

Description

The reconcileFeatures functions provide a facility to post-process a list of features representing a simulated experiment. reconcileFeatures is an S3 generic, new functions can be added for additional types of experiment. The current default is to call reconcileFeatures.SimulatedExperiment which, if called without further arguments, will simply return the feature list unchanged.

Usage

reconcileFeatures(features, ...)
## Default S3 method:
reconcileFeatures(features, ...)
## S3 method for class 'SimulatedExperiment'
reconcileFeatures(features, defaultValues=list(), ...)
## S3 method for class 'NucleosomePosition'
reconcileFeatures(features, defaultMeanDist = 200, ...)

Arguments

features       List of simulated features.
defaultValues  Named list of default parameter values. The method for class SimulatedExperiment ensures that all features have at least the parameters listed in defaultValues, adding them where necessary.
defaultMeanDist Default value for the average distance between nucleosomes for nucleosome positioning experiments.
...             Further arguments to future functions.

Value

A list of features of the same class as features.

makeFeatures, placeFeatures
Examples

```r
set.seed(1)
## generate a (relatively short) sequence of nucleosome features
features <- makeFeatures(length=1e6, )

## check the total length of the features
sum(sapply(features, "[[", "length")) ## 995020

## reconcile features to ensure smooth transitions
## For experiments of class NucleosomePosition this
## also combines some features and introduces
## some overlap between them.
features <- reconcileFeatures(features)

## check the total length of the features again
sum(sapply(features, "[[", "length")) ## 984170
```

---

**sampleReads**

*Sampling sequence read positions from a read density.*

**Description**

Given a read density this function returns the starting positions of sequence reads.

**Usage**

```r
sampleReads(readDens, nreads = 6e+06, strandProb = c(0.5, 0.5))
```

**Arguments**

- `readDens`: A two column matrix of read densities (as produced by `bindDens2readDens`).
- `nreads`: Number of read positions to generate.
- `strandProb`: A numeric vector with two elements giving weights for forward and reverse strand.

**Details**

The expected number of reads for each strand is `strandProb * nreads`.

**Value**

A list with components `fwd` and `rev` giving the read positions on the forward and reverse strand respectively.

**Author(s)**

Peter Humburg

bindDens2readDens

Examples

set.seed(1)

## generate a (relatively short) sequence of nucleosome features
features <- placeFeatures(start=200, length=1e5)

## calculate feature density
featureDens <- feat2dens(features, length=1e5)

## convert to read density
readDens <- bindDens2readDens(featureDens, fragDens, meanLength=160)

## sample reads
## of course you would usually want a much larger number
readPos <- sampleReads(readDens, nreads=1000)

Description

This function acts as driver for the simulation. It takes all required arguments and passes them on to the functions for the different stages of the simulation. The current defaults will simulate a nucleosome positioning experiment.

Usage

simChIP(nreads, genome, file, functions = defaultFunctions(),
control = defaultControl(), verbose = TRUE, load = FALSE)

Arguments

nreads Number of reads to generate.
genome An object of class 'DNASTringSet' or the name of a fasta file containing the genome sequence.
file Base of output file names (see Details).
functions Named list of functions to use for various stages of the simulation, expected names are: ‘features’, ‘bindDens’, ‘readDens’, ‘sampleReads’, ‘readNames’, ‘readSequence’
control Named list of arguments to be passed to simulation functions (one list per function).
verbose Logical indicating whether progress messages should be printed.
load Logical indicating whether an attempt should be made to load intermediate results from a previous run.
Details

The simulation consists of six stages:

1. generate feature sequence (for each chromosome): chromosome length -> feature sequence (list)
2. compute binding site density: feature sequence -> binding site density (vector)
3. compute read density: binding site density -> read density (two column matrix, one column for each strand)
4. sample read start sites: read density -> read positions (list)
5. create read names: number of reads -> unique names
6. obtain read sequence and quality: read positions, genome sequence, [qualities] -> output file

After each of the first three stages the results of the stage are written to a file and can be reused later. File names are created by appending '_features.rdata', '_bindDensity.rdata' and '_readDensity.rdata' to file respectively. Previous results will be loaded for reuse if load is TRUE and files with matching names are found. This is useful to sample repeatedly from the same read density or to recover partial results from an interrupted run.

The creation of files can be prevented by setting file = "". In this case all results will be returned in a list at the end. Note that this will require more memory since all intermediate results have to be held until the end.

The behaviour of the simulation is mainly controlled through the functions and control arguments. They are expected to be lists of the same length with matching names. The names indicate the stage of the simulation for which the function should be used; elements of control will be used as arguments for the corresponding functions.

Value

A list. The components are typically either lists (with one component per chromosome) or file names but note that this may depend on the return value of functions listed in functions. The components of the returned list are:

- features Either a list of generated features or the name of a file containing that list;
- bindDensity Either a list with binding site densities or the name of a file containing that list;
- readDensity Either a list of read densities or the name of a file containing that list;
- readPosition Either a list of read start sites or the name of a file containing that list;
- readSequence The return value of the function listed as 'readSequence'. The default for this the name of the fastq file containing the read sequences;
- readNames Either a list of read names or the name of a file containing that list.

defaultFunctions, defaultControl
Examples

```r
## Not run:
## To run the default nucleosome positioning simulation
## we can simply run something like the line below.
## Of course the file names have to be changed as appropriate.
simChIP(1e7, genome = "reference.fasta", file = "output/sim_10M")

## End(Not run)
```

---

simpleNames  

*Generate unique read names*

Description

Generates a set of unique (and very simple) read names.

Usage

```r
simpleNames(n, nameBase = "read")
```

Arguments

- `n` Number of names to generate.
- `nameBase` Base name to use.

Value

A character vector with entries of the form ‘nameBase_i’ where i runs from 1 to n.

Author(s)

Peter Humburg

Examples

```r
simpleNames(5)
```
## writeFASTQ

Write read sequences and qualities to a FASTQ formatted file

### Description

This is intended to produce the final output of the simulation by providing a fastq file that may then be used in an analysis pipeline.

### Usage

```r
writeFASTQ(read, quality, name, file, append = FALSE)
```

### Arguments

- **read**: List of read sequences.
- **quality**: List of read quality scores.
- **name**: Read names.
- **file**: File name. If this is "" results will be printed to the standard output connection.
- **append**: Logical indicating the reads should be appended to an existing file.

### Details

The first three arguments should have the same length but will be recycled if necessary.

### Value

Called for its side effect.

### Author(s)

Peter Humburg

### See Also

- `readSequence`
- `readQualitySample`
- `writeReads`

### Examples

```r
set.seed(1)

## generate sequence read and quality
quality <- paste(sample(unlist(strsplit(rawToChar(as.raw(33:126)),"")),
36, replace = TRUE), collapse="")
read <- paste(sample(c("A", "C", "G", "T"), 36, replace = TRUE), collapse = "")

## write a fastq record
writeFASTQ(read, quality, "read_1", file="")
```
writeReads  Create fastq file from read positions

Description
This is an interface to pos2fastq that writes all reads for a given genome to a single file.

Usage
writeReads(readPos, readNames, sequence, quality, file, ...)

Arguments
readPos List of read positions with each component holding the read positions for one chromosome, which are themselves two component lists that provide forward and reverse strand positions.
readNames List of the same shape as readPos providing read names.
sequence Genome reference sequence (a DNAStringSet).
quality Read quality scores (see Details).
file Output file.
... Further arguments to pos2fastq.

Details
If quality looks like it might refer to a fastq file an attempt is made to create a ShortReadQ object. The read qualities of any ShortReadQ object passed as quality (directly or indirectly as file name) are extracted and passed on to pos2fastq as quality argument. Otherwise it is passed on unchanged.

Value
The name of the output file.
