Package `GENESIS`

April 16, 2019

Type Package

Title GENetic EStimation and Inference in Structured samples (GENESIS): Statistical methods for analyzing genetic data from samples with population structure and/or relatedness

Version 2.12.4

Date 2018-2-20

Author Matthew P. Conomos, Stephanie M. Gogarten, Lisa Brown, Han Chen, Ken Rice, Tamar Sofer, Timothy Thornton, Chaoyu Yu

Maintainer Stephanie M. Gogarten <sdmorris@uw.edu>

Description The GENESIS package provides methodology for estimating, inferring, and accounting for population and pedigree structure in genetic analyses. The current implementation provides functions to perform PC-AiR (Conomos et al., 2015, Gen Epi) and PC-Relate (Conomos et al., 2016, AJHG). PC-AiR performs a Principal Components Analysis on genome-wide SNP data for the detection of population structure in a sample that may contain known or cryptic relatedness. Unlike standard PCA, PC-AiR accounts for relatedness in the sample to provide accurate ancestry inference that is not confounded by family structure. PC-Relate uses ancestry representative principal components to adjust for population structure/ancestry and accurately estimate measures of recent genetic relatedness such as kinship coefficients, IBD sharing probabilities, and inbreeding coefficients. Additionally, functions are provided to perform efficient variance component estimation and mixed model association testing for both quantitative and binary phenotypes.

**Description**

The GENESIS package provides methodology for estimating, inferring, and accounting for population and pedigree structure in genetic analyses. The current implementation performs PC-AiR (Conomos et al., 2015, Gen Epi) and PC-Relate (Conomos et al., 2016, AJHG). PC-AiR performs a Principal Components Analysis on genome-wide SNP data for the detection of population structure in a sample that may contain known or cryptic relatedness. Unlike standard PCA, PC-AiR accounts for relatedness in the sample to provide accurate ancestry inference that is not confounded by family structure. PC-Relate uses ancestry representative principal components to adjust for population structure/ancestry and accurately estimate measures of recent genetic relatedness such as kinship coefficients, IBD sharing probabilities, and inbreeding coefficients. Additionally, functions are provided to perform efficient variance component estimation and mixed model association testing for both quantitative and binary phenotypes.

**Details**

The PC-AiR analysis is performed using the `pcair` function, which takes genotype data and pairwise measures of kinship and ancestry divergence as input and returns PC-AiR PCs as the output. The function `pcairPartition` is called within `pcair` and uses the PC-AiR algorithm to partition the sample into an ancestry representative ‘unrelated subset’ and ‘related subset’. The function `plot.pcair` can be used to plot pairs of PCs from a class ‘pcair’ object returned by the function `pcair`. The function `kingToMatrix` can be used to convert output text files from the KING software (Manichaikul et al., 2010) into an R matrix of pairwise kinship coefficient estimates in a format that can be used by the functions `pcair` and `pcairPartition`. The PC-Relate analysis is performed using the `pcrelate` function, which takes genotype data and PCs from PC-AiR and returns estimates of kinship coefficients, IBD sharing probabilities, and inbreeding coefficients. There are two functions required to perform SNP genotype association testing with mixed models. First, `fitNullModel` is called to fit the null model (i.e. no SNP genotype term) including fixed effects covariates, such as PC-AiR PCs, and random effects specified by their covariance structures, such as a kinship matrix created from PC-Relate output using `pcrelateToMatrix`. The function `fitNullModel` uses AIREML to estimate variance components for the random effects, and the function `varCompCI` can be used to find confidence intervals on the estimates as well as the proportion of total variability they explain; this allows for heritability estimation. Second, `assocTestSingle` is called with the null model output and the genotype data to perform either Wald or score based association tests.

Description

Run admixture analyses

Usage

admixMap(admixDataList, null.model, verbose=TRUE)

Arguments

- admixDataList: named list of GenotypeIterator objects for each ancestry
- null.model: A null model object returned by fitNullModel.
- verbose: Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details

admixDataList should have one value for each ancestry. See the example for how one might set up this object. List names will propagate to the output file.

Value

data frame with admixture mapping results

Examples

```r
library(GWASTools)
library(gdsfmt)

gdsfile <- system.file("extdata", "HapMap_ASW_MXL_genom.gds", package="GENESIS")
tmpfile <- tempfile()
file.copy(gdsfile, tmpfile)
gds <- openfn.gds(tmpfile, readonly=FALSE)
nsnp <- objdesp.gdsn(index.gdsn(gds, "snp.id"))$dim
nsamp <- objdesp.gdsn(index.gdsn(gds, "sample.id"))$dim
samp <- read.gdsn(index.gdsn(gds, "sample.id"))
dosage_eur <- sample(0:2, nsnp*nsamp, replace=TRUE)
dosage_afr <- ifelse(dosage_eur == 2, 0, sample(0:1, nsnp*nsamp, replace=TRUE))
dosage_amer <- 2 - dosage_eur - dosage_afr
add.gdsn(gds, "dosage_eur", matrix(dosage_eur, nrow=nsamp, ncol=nsnp))
add.gdsn(gds, "dosage_afr", matrix(dosage_afr, nrow=nsamp, ncol=nsnp))
add.gdsn(gds, "dosage_amer", matrix(dosage_amer, nrow=nsamp, ncol=nsnp))
closefn.gds(gds)

# generate a phenotype
set.seed(4)
pheno <- rnorm(nsamp, mean = 0, sd = 1)
covar <- sample(0:1, nsamp, replace=TRUE)

# make ScanAnnotationDataFrame
scanAnnot <- ScanAnnotationDataFrame(data.frame(scanID = samp,
covar, pheno, stringsAsFactors=FALSE))

# read in GDS data
gds <- openfn.gds(tmpfile)
genodataList <- list()
for (anc in c("eur", "afr", "amer")){
  gdsr <- GdsGenotypeReader(gds, genotypeVar=paste("dosage_", anc))
genodataList[[anc]] <- GenotypeData(gdsr, scanAnnot=scanAnnot)
}

# iterators
genolIterators <- lapply(genodataList, GenotypeBlockIterator)

# fit the null mixed model
null.model <- fitNullModel(scanAnnot, outcome = "pheno", covars = "covar")

# run the association test
myassoc <- admixMap(genolIterators, null.model)
close(genodataList[[1]])
unlink(tmpfile)
```

Description

Run admixture analyses. This function is deprecated; use `admixMap` instead.
Usage

admixMapMM(admixDataList, nullMMobj, snp.include = NULL,
  chromosome = NULL, snp.block.size = 5000,
  verbose = TRUE)

Arguments

admixDataList  named list of GenotypeData objects for each ancestry
nullMMobj      A null model object returned by fitNullMM.
snp.include   A vector of SNP IDs to include in the analysis. If NULL, see chromosome for
               further details.
chromosome   A vector of integers specifying which chromosomes to analyze. This parameter
               is only considered when snp.include is NULL; if chromosome is also NULL,
               then all SNPs are included.
snp.block.size The number of SNPs to read-in/analyze at once. The default value is 5000.
verbose        Logical indicator of whether updates from the function should be printed to the
               console; the default is TRUE.

Details

admixDataList should have one value for each ancestry. See the example for how one might set
up this object. List names will propagate to the output file.

Value

data frame with admixture mapping results

## End(Not run)

### Description

`assocTestAggregate` performs aggregate association tests using the null model fit with `fitNullModel`.

### Usage

```r
## S4 method for signature 'SeqVarIterator'
assocTestAggregate(gdsobj, null.model, AF.max=1, weight.beta=c(1,1), weight.user=NULL,
```
assocTestAggregate

test=c("Burden", "SKAT", "SMMAT"),
burden.test=c("Score", "Wald"), rho=0,
pval.method=c("davies", "kuonen", "liu"),
sparse=TRUE, verbose=TRUE)

## S4 method for signature 'GenotypeIterator'
assocTestAggregate(gdsobj, null.model, AF.max=1,
weight.beta=c(1,1), weight.user=NULL,
test=c("Burden", "SKAT", "SMMAT"),
burden.test=c("Score", "Wald"), rho=0,
pval.method=c("davies", "kuonen", "liu"),
verbose=TRUE)

Arguments

gdsobj An object of class SeqVarIterator from the package SeqVarTools containing the genotype data for the variants and samples to be used for the analysis.

null.model A null model object returned by fitNullModel.

AF.max A numeric value specifying the upper bound on the alternate allele frequency for variants to be included in the analysis.

weight.beta A numeric vector of length two specifying the two parameters of the Beta distribution used to determine variant weights; weights are given by `dbeta(MAF, a, b)`, where MAF is the minor allele frequency, and `a` and `b` are the two parameters specified here. `weight.beta = c(1,25)` gives the Wu weights; `weight.beta = c(0.5, 0.5)` is proportional to the Madsen-Browning weights; and `weight.beta = c(1,1)` gives a weight of 1 to all variants. This input is ignored when `weight.user` is not NULL.

weight.user A character string specifying the name of a variable to be used as variant weights. This variable can be in either 1) the `variantData` slot of `gdsobj` or 2) the `mcols` of the GRanges or GRangesList object used to create `gdsobj` (when `gdsobj` is a link(SeqVarRangeIterator) or link(SeqVarListIterator)). When left NULL (the default), the weights specified by `weight.beta` will be used.

test A character string specifying the type of test to be performed. The possibilities are "Burden" (default), "SKAT", or "SMMAT". When this is set to "SKAT" and the parameter `rho` has multiple values, a SKAT-O test is performed.

burden.test A character string specifying the type of Burden test to perform when `test` = "Burden". The possibilities are "Score" and "Wald". "Score" can be used for any null.model. "Wald" can not be used when the null.model is from a mixed model with a binary outcome variable.

rho A numeric value (or vector of numeric values) in $[0,1]$ specifying the rho parameter for SKAT. When `rho = 0`, a standard SKAT test is performed. When `rho = 1`, a score burden test is performed. When `rho` is a vector of values, SKAT-O is performed using each of those values as the search space for the optimal rho.

pval.method A character string specifying which method to use to calculate SKAT p-values. "davies" (the default) uses numerical integration; "kuonen" uses a saddle-point method; and "liu" uses a moment matching approximation. If the davies method generates an error, kuonen is tried, and then liu as a last resort.

sparse Logical indicator of whether to read genotypes as sparse Matrix objects: the default is TRUE. Set this to FALSE if the alternate allele dosage of the genotypes in the test are not expected to be mostly 0.
verbose Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details

The type of aggregate unit tested depends on the class of iterator used for gdsobj. Options include sliding windows, specific ranges of variants or selection of individual variants (ranges with width 1). See SeqVarIterator for more details.

The effect size estimate is for each copy of the alternate allele. For multiallelic variants, each alternate allele is tested separately.

Somewhat similarly to SKAT-O, the variant Set Mixed Model Association Test (SMMAT, Chen et al., manuscript in preparation) combines the burden test p-value with an adjusted SKAT (which is asymptotically independent of the burden test) p-value using a chi-square distribution with 4df from Fisher’s method.

Value

A list with the following items:

results A data.frame containing the results from the main analysis. Each row is a separate aggregate test:

If gdsobj is a SeqVarWindowIterator:

chr The chromosome value
start The start position of the window
date The end position of the window

Always:
n.site The number of variant sites included in the test.
n.alt The number of alternate alleles included in the test.
n.sample.alt The number of samples with an observed alternate allele at any variant in the aggregate set.

If test is "Burden":

If burden.test is "Score":

Score The value of the score function
Score.SE The estimated standard error of the Score
Score.Stat The score Z test statistic
Score.pval The score p-value

If burden.test is "Wald":

Est The effect size estimate for a one unit increase in the burden value
Est.SE The estimated standard error of the effect size estimate
Wald.Stat The Wald Z test statistic
Wald.pval The Wald p-value

If test is "SKAT":

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Q_rho</td>
<td>The SKAT test statistic for the value of rho specified. There will be as many of these variables as there are rho values chosen.</td>
</tr>
<tr>
<td>pval_rho</td>
<td>The SKAT p-value for the value of rho specified. There will be as many of these variables as there are rho values chosen.</td>
</tr>
<tr>
<td>err_rho</td>
<td>Takes value 1 if there was an error in calculating the p-value for the value of rho specified when using the &quot;kuonen&quot; or &quot;davies&quot; methods; 0 otherwise. When there is an error, the p-value returned is from the &quot;liu&quot; method. There will be as many of these variables as there are rho values chosen.</td>
</tr>
</tbody>
</table>

When length(rho) > 1 and SKAT-O is performed:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>min.pval</td>
<td>The minimum p-value among the p-values calculated for each choice of rho.</td>
</tr>
<tr>

assocTestMM

---

**Description**

assocTestMM performs SNP genotype association tests using the null model fit with fitNullMM. This function is deprecated; use assocTestSingle instead.

**Usage**

```r
assocTestMM(genoData, nullMMobj, test = "Wald", snp.include = NULL,
            chromosome = NULL, impute.geno = TRUE, snp.block.size = 5000,
            ivars = NULL, ivar.return.betaCov = FALSE, verbose = TRUE)
```

**Arguments**

- `genoData` An object of class GenotypeData from the package GWASTools containing the genotype data for SNPs and samples to be used for the analysis. This object can easily be created from a matrix of SNP genotype data, PLINK files, or GDS files. Alternatively, this could be an object of class SeqVarData from the package SeqVarTools containing the genotype data for the sequencing variants and samples to be used for the analysis.
- `nullMMobj` A null model object returned by fitNullMM.
- `test` A character string specifying the type of test to be performed. The possibilities are "Wald" (default) or "Score"; only "Score" can be used when the family of the null model fit with fitNullMM is not gaussian.
- `snp.include` A vector of SNP IDs to include in the analysis. If NULL, see chromosome for further details.
- `chromosome` A vector of integers specifying which chromosomes to analyze. This parameter is only considered when snp.include is NULL; if chromosome is also NULL, then all SNPs are included.
- `impute.geno` A logical indicator of whether sporadic missing genotype values should be mean imputed. The default is TRUE. See `Details` for further information.
- `snp.block.size` The number of SNPs to read-in/analyze at once. The default value is 5000. See `Details` for further information regarding how this parameter works when impute.geno is FALSE.
- `ivars` A vector of character strings specifying the names of the variables for which a genotype interaction term should be included. If NULL (default) no genotype interactions are included. See `Details` for further information.
assocTestMM

ivar.return.betaCov

Logical indicator of whether the estimated covariance matrix of the effect size estimates (betas) for the genotype and genotype interaction terms should be returned; the default is FALSE.

verbose

Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details

When impute.geno is TRUE, sporadic missing genotype values are mean imputed using the minor allele frequency (MAF) calculated on all other samples at that SNP. When impute.geno is FALSE, samples with missing values for all of the SNP genotypes in the current SNP block are removed from the analysis for the block; this may significantly slow down computation time because many pre-computed matrices need to be re-computed each time the sample set changes. Also note: when impute.geno is FALSE, sporadic missingness for a sample inside of a SNP block will lead to an error.

The input ivars can be used to perform GxE tests. Multiple interaction variables may be specified, but all interaction variables specified must have been included as covariates in fitting the null model with fitNullMM. When performing GxE analyses, assocTestMM will report two tests: (1) the joint test of all genotype interaction terms in the model (this is the test for any genotype interaction effect), and (2) the joint test of the genotype term along with all of the genotype interaction terms (this is the test for any genetic effect). Individual genotype interaction terms can be tested by creating Wald test statistics from the reported effect size estimates and their standard errors (Note: when ivars contains a single continuous or binary covariate, this test is the same as the test for any genotype interaction effect mentioned above). In order to test more complex hypotheses regarding subsets of multiple genotype interaction terms, ivar.return.betaCov can be used to retrieve the estimated covariance matrix of the effect size estimates.

Value

A data.frame where each row refers to a different SNP with the columns:

- snpID: The SNP ID
- chr: The numeric chromosome value
- n: The number of samples used to analyze the SNP
- MAF: The estimated minor allele frequency
- minor.allele: Either "A" or "B" indicating which allele is the minor allele

If test is "Score":

- Score: The value of the score function
- Var: The variance of the score function
- Score.Stat: The score chi-squared test statistic
- Score.pval: The score p-value

If test is "Wald" and ivars is NULL:

- Est: The effect size estimate for each additional copy of the "A" allele
- SE: The estimated standard error of the effect size estimate
- Wald.Stat: The Wald chi-squared test statistic
- Wald.pval: The Wald p-value
If `test` is "Wald" and `ivars` is not `NULL`:

- **Est.G**: The effect size estimate for the genotype term.
- **Est.G:ivar**: The effect size estimate for the genotype*ivar interaction term. There will be as many of these terms as there are interaction variables, and "ivar" will be replaced with the variable name.
- **SE.G**: The estimated standard error of the genotype term effect size estimate.
- **SE.G:ivar**: The estimated standard error of the genotype*ivar effect size estimate. There will be as many of these terms as there are interaction variables, and "ivar" will be replaced with the variable name.
- **GxE.Stat**: The Wald chi-squared test statistic for the test of all genotype interaction terms. When there is only one genotype interaction term, this is the test statistic for that term.
- **GxE.pval**: The Wald p-value for the test of all genotype interaction terms; i.e. the test of any genotype interaction effect.
- **Joint.Stat**: The Wald chi-squared test statistic for the joint test of the genotype term and all of the genotype interaction terms.
- **Joint.pval**: The Wald p-value for the joint test of the genotype term and all of the genotype interaction terms; i.e. the test of any genotype effect.

When `ivars` is not `NULL`, if `ivar.return.betaCov` is `TRUE`, then the output is a list with two elements. The first, "results", is the data.frame described above. The second, "betaCov", is a list with length equal to the number of rows of "results", where each element of the list is the covariance matrix of the effect size estimates (betas) for the genotype and genotype interaction terms.

If `genoData` is a `SeqVarData` object, the effect size estimate is for each copy of the alternate allele.

**Note**

The GenotypeData function in the GWASTools package should be used to create the input genoData. Input to the GenotypeData function can easily be created from an R matrix or GDS file. PLINK .bed, .bim, and .fam files can easily be converted to a GDS file with the function snpgdsBED2GDS in the SNPRelate package. Alternatively, the SeqVarData function in the SeqVarTools package can be used to create the input genodata when working with sequencing data.

Examples

```r
## Not run:
library(GWASTools)

# file path to GDS file
gdsfile <- system.file("extdata", "HapMap_ASW_MXL_geno.gds", package="GENESIS")
# read in GDS data
HapMap_geno <- GdsGenotypeReader(filename = gdsfile)
# create a GenotypeData class object
HapMap_genoData <- GenotypeData(HapMap_geno)
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")

# run PC-AiR
mypcair <- pcair(genoData = HapMap_genoData, kinMat = HapMap_ASW_MXL_KINGmat,
                 divMat = HapMap_ASW_MXL_KINGmat)

# run PC-Relate
mypcrel <- pcrelate(genoData = HapMap_genoData, pcMat = mypcair$vectors[,1],
                   training.set = mypcair$unrels)

# generate a phenotype
set.seed(4)
pheno <- 0.2*mypcair$vectors[,1] + rnorm(mypcair$nsamp, mean = 0, sd = 1)

# make ScanAnnotationDataFrame
scanAnnot <- ScanAnnotationDataFrame(data.frame(scanID = mypcrel$sample.id,
                                             pc1 = mypcair$vectors[,1],
                                             pheno = pheno))

# make covMatList
covMatList <- list("Kin" = pcrelateMakeGRM(mypcrel))

# fit the null mixed model
nullmod <- fitNullMM(scanData = scanAnnot, outcome = "pheno", covars = "pc1",
                     covMatList = covMatList)

# run the association test
myassoc <- assocTestMM(genoData = HapMap_genoData, nullMMobj = nullmod)
close(HapMap_genoData)

# make a QQ plot
qqPlot(myassoc$Wald.pval)
## End(Not run)
```

assocTestSingle  Genotype Association Testing with Mixed Models

Description

assocTestSingle performs genotype association tests using the null model fit with fitNullModel.

Usage

```r
## S4 method for signature 'SeqVarIterator'
```
assocTestSingle(gdsobj, null.model, test=c("Score", "Wald"),
GxE=NULL, sparse=TRUE, verbose=TRUE)

## S4 method for signature 'GenotypeIterator'
assocTestSingle(gdsobj, null.model, test=c("Score", "Wald"),
GxE=NULL, verbose=TRUE)

**Arguments**

- **gdsobj**: An object of class `SeqVarIterator` from the package `SeqVarTools`, or an object of class `GenotypeIterator` from the package `GWASTools`, containing the genotype data for the variants and samples to be used for the analysis.

- **null.model**: A null model object returned by `fitNullModel`.

- **test**: A character string specifying the type of test to be performed. The possibilities are "Score" (default) or "Wald"; only "Score" can be used when the family of the null model fit with `fitNullModel` is not gaussian.

- **GxE**: A vector of character strings specifying the names of the variables for which a genotype interaction term should be included. If NULL (default) no genotype interactions are included. See 'Details' for further information.

- **sparse**: Logical indicator of whether to read genotypes as sparse Matrix objects; the default is TRUE. Set this to FALSE if the alternate allele dosage of the genotypes in the test are not expected to be mostly 0.

- **verbose**: Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

**Details**

Sporadic missing genotype values are mean imputed using the minor allele frequency (MAF) calculated on all other samples at that variant.

The input GxE can be used to perform GxE tests. Multiple interaction variables may be specified, but all interaction variables specified must have been included as covariates in fitting the null model with `fitNullModel`. When performing GxE analyses, `assocTestSingle` will report two tests: (1) the joint test of all genotype interaction terms in the model (this is the test for any genotype interaction effect), and (2) the joint test of the genotype term along with all of the genotype interaction terms (this is the test for any genetic effect). Individual genotype interaction terms can be tested by creating Wald test statistics from the reported effect size estimates and their standard errors (Note: when GxE contains a single continuous or binary covariate, this test is the same as the test for any genotype interaction effect mentioned above).

**Value**

A data.frame where each row refers to a different variant with the columns:

- **variant.id**: The variant ID
- **chr**: The chromosome value
- **pos**: The base pair position
- **allele.index**: The index of the alternate allele. For biallelic variants, this will always be 1.
- **n.obs**: The number of samples with non-missing genotypes
- **freq**: The estimated alternate allele frequency

If test is "Score":

```r
assocTestSingle(gdsobj, null.model, test=c("Score", "Wald"),
GxE=NULL, sparse=TRUE, verbose=TRUE)
```
### assocTestSingle

fitNullMM

Fit a Mixed Model Under the Null Hypothesis

Description

fitNullMM fits a mixed model with random effects specified by their covariance structures; this allows for the inclusion of a polygenic random effect using a kinship matrix or genetic relationship matrix (GRM). The output of fitNullMM can be used to estimate genetic heritability and can be passed to assocTestMM for the purpose of genetic association testing. This function is deprecated; use fitNullModel instead.
Usage

fitNullMM(scanData, outcome, covars = NULL, covMatList, scan.include = NULL, 
family = gaussian, group.var = NULL, start = NULL, 
AIREML.tol = 1e-6, maxIter = 100, dropZeros = TRUE, verbose = TRUE)

Arguments

scanData	An object of class ScanAnnotationDataFrame from the package GWASTools, 
AnnotatedDataFrame, or class data.frame containing the outcome and co-
variate data for the samples to be used for the analysis. scanData must have a
column scanID containing unique IDs for all samples.
outcome	A character string specifying the name of the outcome variable in scanData.
covars	A vector of character strings specifying the names of the fixed effect covariates 
in scanData; an intercept term is automatically included. If NULL (default) the 
only fixed effect covariate is the intercept term.
covMatList	A list of matrices specifying the covariance structures of the random effects 
terms. The column and row names of each of these matrices must match the 
scanIDs from scanData. If only one random effect is being used, a single matrix 
(not in a list) can be used. See 'Details' for more information.
scan.include	A vector of scanIDs for samples to include in the analysis. If NULL, all samples 
in scanData are included.
family	A description of the error distribution to be used in the model. The default 
"gaussian" fits a linear mixed model; see family for further options, and see 
'Details' for more information.
group.var	This variable can only be used when family = gaussian. A character string 
specifying the name of a categorical variable in scanData that is used to fit het-
erogeneous residual error variances. If NULL (default), then a standard LMM 
with constant residual variance for all samples is fit. See 'Details' for more 
information.
start	A vector of starting values for the variance component estimation procedure. 
The function will pick reasonable starting values when left NULL (default). See 
'Details' for more information.
AIREML.tol	The convergence threshold for the Average Information REML (AIREML) pro-
cedure used to estimate the variance components of the random effects. See 
'Details' for more information.
maxIter	The maximum number of iterations allowed in the AIREML procedure.
dropZeros	Logical indicator of whether variance component terms that converge to 0 should 
be removed from the model; the default is TRUE. See 'Details' for more infor-
mentation.
verbose	Logical indicator of whether updates from the function should be printed to the 
console; the default is TRUE.

Details

covMatList is used to specify the covariance structures of the random effects terms in the model. 
For example, to include a polygenic random effect, one matrix in covMatList could be a kinship 
matrix or a genetic relationship matrix (GRM). As another example, to include household membership 
as a random effect, one matrix in covMatList should be a 0/1 matrix with a 1 in the [i,j] and
[j,i] entries if individuals i and j are in the same household and 0 otherwise; the diagonals of such a matrix should all be 1.

When family is not gaussian, the penalized quasi-likelihood (PQL) approximation to the generalized linear mixed model (GLMM) is fit following the procedure of GMMAT (Chen et al.). For some outcomes, there may be evidence that different groups of observations have different residual variances, and the standard LMM assumption of homoscedasticity is violated. When group.var is specified, separate (heterogeneous) residual variance components are fit for each unique value of group.var.

Let m be the number of matrices in covMatList and let g be the number of categories in the variable specified by group.var. The length of the start vector must be (m + 1) when family is gaussian and group.var is NULL; (m + g) when family is gaussian and group.var is specified; or m when family is not gaussian.

A Newton-Raphson iterative procedure with Average Information REML (AIREML) is used to estimate the variance components of the random effects. When the Euclidean distance between the new and previous variance component estimates is less than AIREML.tol, the algorithm declares convergence of the estimates. Sometimes a variance component may approach the boundary of the parameter space at 0; step-halving is used to prevent any component from becoming negative. However, when a variance component gets near the 0 boundary, the algorithm can sometimes get "stuck", preventing the other variance components from converging; if dropZeros is TRUE, then variance components that converge to a value less than AIREML.tol will be dropped from the model and the estimation procedure will continue with the remaining variance components.

Value

An object of class 'GENESIS.nullMixedModel'. A list including:

- varComp: The variance component estimates. There is one variance component for each random effect specified in covMatList. When family is gaussian, there are additional residual variance components: one residual variance component when group.var is NULL, and as many residual variance components as there are unique values of group.var when it is specified.
- varCompCov: The estimated covariance matrix of the variance component estimates given by varComp. This can be used for hypothesis tests regarding the variance components.
- fixef: A data.frame with effect size estimates (betas), standard errors, chi-squared test statistics, and p-values for each of the fixed effect covariates specified in covars.
- betaCov: The estimated covariance matrix of the effect size estimates (betas) of the fixed effect covariates. This can be used for hypothesis tests regarding the fixed effects.
- fitted.values: The fitted values from the mixed model; i.e. W*beta where W is the design matrix and beta are the effect size estimates for the fixed effects.
- resid.marginal: The marginal residuals from the mixed model; i.e. Y - W*beta where Y is the vector of outcome values.
- eta: The linear predictor from the mixed model; i.e. W*beta + Z*u where Z*u specifies the effects of the random effects.
- resid.conditional: The conditional residuals from the mixed model; i.e. Y - W*beta - Z*u.
- logLikR: The restricted log-likelihood value.
- logLik: The log-likelihood value.
The Akaike Information Criterion value.

The residual sum of squares from the model fit. When family is gaussian, this will typically be 1 since the residual variance component is estimated separately.

The "working" outcome vector. When family is gaussian, this is just the original outcome vector. When family is not gaussian, this is the PQL linearization of the outcome vector. This is used by assocTestMM for genetic association testing. See 'Details' for more information.

The original outcome vector. When family is gaussian, this is equal to workingY.

The design matrix for the fixed effect covariates used in the model.

The Cholesky decomposition of the inverse of the estimated outcome covariance structure. This is used by assocTestMM for genetic association testing.

A vector of scanIDs for the samples used in the analysis.

A character string specifying the family used in the analysis.

A logical indicator of whether the AIREML procedure for estimating the random effects variance components converged.

A vector of logicals the same length as varComp specifying whether the corresponding variance component estimate was set to 0 by the function due to convergence to the boundary in the AIREML procedure.

A logical indicator of whether heterogeneous residual variance components were used in the model (specified by group.var).

The call to fitNullMM.

Matthew P. Conomos

varCompCI for estimating confidence intervals for the variance components and the proportion of variability (heritability) they explain, assocTestMM for running mixed model genetic association tests using the output from fitNullMM. GWASTools for a description of the package containing the ScanAnnotationDataFrame class.

Examples

```r
## Not run:
library(GWASTools)

# file path to GDS file
```
gdsfile <- system.file("extdata", "HapMap_ASW_MXL_geno.gds", package="GENESIS")
# read in GDS data
HapMap_geno <- GdsGenotypeReader(filename = gdsfile)
# create a GenotypeData class object
HapMap_genoData <- GenotypeData(HapMap_geno)
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")

# run PC-AiR
mypcair <- pcair(genoData = HapMap_genoData, kinMat = HapMap_ASW_MXL_KINGmat,
                  divMat = HapMap_ASW_MXL_KINGmat)

# run PC-Relate
mypcrel <- pcrelate(genoData = HapMap_genoData, pcMat = mypcair$vectors[,1],
                    training.set = mypcair$unrels)
close(HapMap_genoData)

set.seed(4)
pheno <- 0.2*mypcair$vectors[,1] + rnorm(mypcair$nsamp, mean = 0, sd = 1)

# make ScanAnnotationDataFrame
scanAnnot <- ScanAnnotationDataFrame(data.frame(scanID = mypcrel$sample.id,
                                            pc1 = mypcair$vectors[,1],
                                            pheno = pheno))

# make covMatList
covMatList <- list("Kin" = pcrelateMakeGRM(mypcrel))

# fit the null mixed model
nullmod <- fitNullMM(scanData = scanAnnot, outcome = "pheno", covars = "pc1",
                     covMatList = covMatList)

## End(Not run)

fitNullModel

Fit a Model Under the Null Hypothesis

Description

fitNullModel fits a regression model or a mixed model with random effects specified by their covariance structures; this allows for the inclusion of a polygenic random effect using a kinship matrix or genetic relationship matrix (GRM). The output of fitNullModel can be used to estimate genetic heritability and can be passed to assocTestSingle or assocTestAggregate for the purpose of genetic association testing.

nullModelInvNorm does an inverse normal transform of a previously fit null model.

Usage

## S4 method for signature 'data.frame'
fitNullModel(x, outcome, covars = NULL, cov.mat = NULL,
             group.var = NULL, family = "gaussian", start = NULL,
             AIREML.tol = 1e-6, max.iter = 100, drop.zeros = TRUE, verbose = TRUE)

## S4 method for signature 'AnnotatedDataFrame'
fitNullModel(x, outcome, covars = NULL, cov.mat = NULL,
arguments

- **x**: An object of class `data.frame`, `AnnotatedDataFrame`, or `SeqVarData` containing the outcome and covariate data for the samples to be used for the analysis.
- **outcome**: A character string specifying the name of the outcome variable in `x`.
- **covars**: A vector of character strings specifying the names of the fixed effect covariates in `x`; an intercept term is automatically included. If `NULL` (default) the only fixed effect covariate is the intercept term.
- **cov.mat**: A matrix or list of matrices specifying the covariance structures of the random effects terms. Objects from the `Matrix` package are supported. See ‘Details’ for more information.
- **group.var**: This variable can only be used when `family = "gaussian"`. A character string specifying the name of a categorical variable in `x` that is used to fit heterogeneous residual error variances. If `NULL` (default), then a standard LMM with constant residual variance for all samples is fit. See ‘Details’ for more information.
- **sample.id**: A vector of IDs for samples to include in the analysis. If `NULL`, all samples in `x` are included.
- **family**: A description of the error distribution to be used in the model. The default "gaussian" fits a linear model; see `family` for further options, and see ‘Details’ for more information.
- **start**: A vector of starting values for the variance component estimation procedure. The function will pick reasonable starting values when left `NULL` (default). See ‘Details’ for more information.
- **AIREML.tol**: The convergence threshold for the Average Information REML (AIREML) procedure used to estimate the variance components of the random effects. See ‘Details’ for more information.
- **max.iter**: The maximum number of iterations allowed in the AIREML procedure.
- **drop.zeros**: Logical indicator of whether variance component terms that converge to 0 should be removed from the model; the default is `TRUE`. See ‘Details’ for more information.
- **verbose**: Logical indicator of whether updates from the function should be printed to the console; the default is `TRUE`.
- **...**: Arguments to pass to other methods.
- **null.model**: The output of `fitNullModel`.
- **norm.option**: Whether the normalization should be done separately within each value of `group.var` ("by.group") or with all samples together ("all").
rescale

Controls whether to rescale the variance for each group after inverse-normal transform, restoring it to the original variance before the transform. "none" for no rescaling of the residuals; "model" for model-based rescaling, and "residSD" to rescale to the standard deviation of the marginal residuals.

Details

cov.mat is used to specify the covariance structures of the random effects terms in the model. For example, to include a polygenic random effect, one matrix in cov.mat could be a kinship matrix or a genetic relationship matrix (GRM). As another example, to include household membership as a random effect, one matrix in cov.mat should be a 0/1 matrix with a 1 in the [i,j] and [j,i] entries if individuals i and j are in the same household and 0 otherwise; the diagonals of such a matrix should all be 1.

When family is not gaussian, the penalized quasi-likelihood (PQL) approximation to the generalized linear mixed model (GLMM) is fit following the procedure of GMMAT (Chen et al.). For some outcomes, there may be evidence that different groups of observations have different residual variances, and the standard LMM assumption of homoscedasticity is violated. When group.var is specified, separate (heterogeneous) residual variance components are fit for each unique value of group.var.

Let m be the number of matrices in cov.mat and let g be the number of categories in the variable specified by group.var. The length of the start vector must be (m + 1) when family is gaussian and group.var is NULL; (m + g) when family is gaussian and group.var is specified; or m when family is not gaussian.

A Newton-Raphson iterative procedure with Average Information REML (AIREML) is used to estimate the variance components of the random effects. When the Euclidean distance between the new and previous variance component estimates is less than AIREML.tol, the algorithm declares convergence of the estimates. Sometimes a variance component may approach the boundary of the parameter space at 0; step-halving is used to prevent any component from becoming negative. However, when a variance component gets near the 0 boundary, the algorithm can sometimes get "stuck", preventing the other variance components from converging; if drop.zeros is TRUE, then variance components that converge to a value less than AIREML.tol will be dropped from the model and the estimation procedure will continue with the remaining variance components.

Value

An object of class 'GENESIS.nullModel' or 'GENESIS.nullMixedModel'. A list including:

family A character string specifying the family used in the analysis.
hetResid A logical indicator of whether heterogeneous residual variance components were used in the model (specified by group.var).
varComp The variance component estimates. There is one variance component for each random effect specified in cov.mat. When family is gaussian, there are additional residual variance components; one residual variance component when group.var is NULL, and as many residual variance components as there are unique values of group.var when it is specified.
varCompCov The estimated covariance matrix of the variance component estimates given by varComp. This can be used for hypothesis tests regarding the variance components.
fixef A data.frame with effect size estimates (betas), standard errors, chi-squared test statistics, and p-values for each of the fixed effect covariates specified in covars.
fitNullModel

betaCov
The estimated covariance matrix of the effect size estimates (betas) of the fixed effect covariates. This can be used for hypothesis tests regarding the fixed effects.

fitted.values
The fitted values from the model; i.e. W*beta where W is the design matrix and beta are the effect size estimates for the fixed effects.

resid.marginal
The marginal residuals from the model; i.e. Y - W*beta where Y is the vector of outcome values.

resid.conditional
The conditional residuals from the model; i.e. Y - W*beta - Z*u.

logLik
The log-likelihood value.

logLikR
The restricted log-likelihood value.

AIC
The Akaike Information Criterion value.

workingY
The "working" outcome vector. When family is gaussian, this is just the original outcome vector. When family is not gaussian, this is the PQL linearization of the outcome vector. This is used by assocTestSingle or assocTestAggregate for genetic association testing. See 'Details' for more information.

outcome
The original outcome vector, as a 1-column matrix with column name. When family is gaussian, this is equal to workingY.

model.matrix
The design matrix for the fixed effect covariates used in the model.

group.idx
If group.var is not NULL, a list of indices for samples in each group.

cholSigmaInv
The Cholesky decomposition of the inverse of the estimated outcome covariance structure. This is used by assocTestSingle or assocTestAggregate for genetic association testing.

converged
A logical indicator of whether the AIREML procedure for estimating the random effects variance components converged.

zeroFLAG
A vector of logicals the same length as varComp specifying whether the corresponding variance component estimate was set to 0 by the function due to convergence to the boundary in the AIREML procedure.

RSS
The residual sum of squares from the model fit. When family is gaussian, this will typically be 1 since the residual variance component is estimated separately.

sample.id
A vector of IDs for the samples used in the analysis.

fitNullReg

Fit a Regression Model Under the Null Hypothesis

Description

`fitNullReg` fits a regression model. The output of `fitNullReg` can be passed to `assocTestSeq` or `assocTestSeqWindow` for the purpose of genetic association testing. This function is deprecated; use `fitNullModel` instead.

Usage

```r
fitNullReg(scanData, outcome, covars = NULL, scan.include = NULL,
           family = gaussian, verbose = TRUE)
```
fitNullReg

Arguments

scanData An object of class ScanAnnotationDataFrame from the package GWASTools, AnnotatedDataFrame, or class data.frame containing the outcome and covariate data for the samples to be used for the analysis. scanData must have a column scanID containing unique IDs for all samples.

outcome A character string specifying the name of the outcome variable in scanData.

covars A vector of character strings specifying the names of the fixed effect covariates in scanData; an intercept term is automatically included. If NULL (default) the only fixed effect covariate is the intercept term.

scan.include A vector of scanIDs for samples to include in the analysis. If NULL, all samples in scanData are included.

family A description of the error distribution to be used in the model. The default "gaussian" fits a linear model; see family for further options.

verbose Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Value

An object of class 'GENESIS.nullModel'. A list including:

fixef A data.frame with effect size estimates (betas), standard errors, chi-squared test statistics, and p-values for each of the fixed effect covariates specified in covars.

betaCov The estimated covariance matrix of the effect size estimates (betas) of the fixed effect covariates. This can be used for hypothesis tests regarding the fixed effects.

resid.response The residuals from the model.

logLik The log-likelihood value.

AIC The Akaike Information Criterion value.

workingY The "working" outcome vector. When family is gaussian, this is just the original outcome vector. When family is not gaussian, this is the PQL linearization of the outcome vector. This is used by assocTestSeq for genetic association testing.

model.matrix The design matrix for the fixed effect covariates used in the model.

aliased Coefficients removed from the model.

sigma Variance of the model.

scanID A vector of scanIDs for the samples used in the analysis.

family A character string specifying the family used in the analysis.

GENESIS-defunct

Defunct functions in package GENESIS

Description

These functions are defunct and no longer available.

Details

The following functions are defunct; use the replacement indicated below:

- assocTestSeq: assocTestAggregate
- assocTestSeqWindow: assocTestAggregate

GENESIS-deprecated

Deprecated functions in package GENESIS

Description

These functions are provided for compatibility with older versions of GENESIS only, and will be defunct at the next release.

Details

The following functions are deprecated and will be made defunct; use the replacement indicated below:

- admixMapMM: admixMap
- assocTestMM: assocTestSingle
- fitNullMM: fitNullModel
- fitNullReg: fitNullModel
- king2mat: kingToMatrix
- pcrelateMakeGRM: pcrelateToMatrix
- pcrelateReadInbreed: pcrelate
- pcrelateReadKinship: pcrelate
HapMap_ASW_MXL_KINGmat

**Description**

KING-robust kinship coefficient estimates for the combined HapMap African Americans in the Southwest U.S. (ASW) and Mexican Americans in Los Angeles (MXL) samples.

**Usage**

```r
data(HapMap_ASW_MXL_KINGmat)
```

**Format**

The format is: num [1:173, 1:173] 0 0.00157 -0.00417 0.00209 0.00172 ...

**Value**

A matrix of pairwise kinship coefficient estimates as calculated with KING-robust for the combined HapMap African Americans in the Southwest U.S. (ASW) and Mexican Americans in Los Angeles (MXL) samples.

**Source**

**References**

---

**kin2gds**

*Store kinship matrix in GDS*

**Description**

kin2gds and mat2gds write kinship matrices to GDS files.

**Usage**

```r
kinesis2gds(ibdobj, gdsfile)
mat2gds(mat, gdsfile)
```

**Arguments**

- `ibdobj`: A list with elements `sample.id` and `kinship`, such as the output of `snpgdsIBDKING`.
- `mat`: A matrix with sample identifiers in colnames.
- `gdsfile`: A character string with the name of the GDS file to create.
when using pcair or pcairPartition with large sample sizes, it can be more memory efficient to read data from GDS files. kin2gds and mat2gds store kinship matrices in GDS files for use with these functions.

king2mat

Convert KING text output to an R Matrix

Description

king2mat is used to extract the pairwise kinship coefficient estimates or IBS0 values from the output text files of KING and put them into an R object of class matrix that can be read by the functions pcair and pcairPartition. This function is deprecated; use kingToMatrix instead.

Usage

king2mat(file.kin0, file.kin = NULL, iids = NULL,
      type = "kinship", verbose = TRUE)
Arguments

file.kin0  File name of the .kin0 text file output from KING.
file.kin   Optional file name of the .kin text file output from KING.
iids      An optional vector of individual IDs in the same order as desired for the output matrix. See 'Details' for more information.
type      Character string taking the values "kinship" (default) or "IBS0", to inform the function to read in kinship coefficients or IBS0 values from the KING output.
verbose   A logical indicating whether or not to print status updates to the console; the default is TRUE.

Details

When using the function pcair, it is important that the order of individuals in the kinMat matrix matches the order of individuals in genoData. The KING software has a tendency to reorder individuals. If iids = NULL, the default is for the order to be taken from the KING output text file. By specifying iids the user can control the order of individuals in the output matrix. The IDs used for iids must be the same set of character IDs that are output as columns 'ID1' and 'ID2' in the KING output text files; all of the IDs specified in iids must be in the KING output, and all IDs in the KING output must be specified in iids.

Value

An object of class 'matrix' with pairwise kinship coefficients or IBS0 values as estimated by KING for each pair of individuals in the sample. The estimates are on both the upper and lower triangle of the matrix, and the diagonal is arbitrarily set to 0.5. Individual IDs are set as the column and row names of the matrix.

file.kin <- system.file("extdata", "MXL_ASW.kin", package="GENESIS")
KINGmat <- king2mat(file.kin0 = file.kin0, file.kin = file.kin, type="kinship")
## End(Not run)
```
kingToMatrix

Convert KING text output to an R Matrix

Description

kingToMatrix is used to extract the pairwise kinship coefficient estimates from the output text files of KING –ibdseg or KING –robust and put them into an R object of class Matrix. One use of this matrix is that it can be read by the functions pcair and pcairPartition.

Usage

## S4 method for signature 'character'
kingToMatrix(king, sample.include = NULL, thresh = NULL, verbose = TRUE)
## S4 method for signature 'snpGdsIBDClass'
kingToMatrix(king, sample.include = NULL, thresh = NULL, verbose = TRUE)

Arguments

king Output from KING, either a snpGdsIBDClass object from snpGdsIBDKING or a character vector of one or more file names output from the command-line version of KING; see ‘Details’.

sample.include An optional vector of sample.id indicating all samples that should be included in the output matrix; see ‘Details’ for usage.

thresh Kinship threshold for clustering samples to make the output matrix sparse block-diagonal. When NULL, no clustering is done. See ‘Details’.

verbose A logical indicating whether or not to print status updates to the console; the default is TRUE.

Details

king can be a vector of multiple file names if your KING output is stored in multiple files; e.g. KING –robust run with family IDs returns a .kin and a .kin0 file for pairs within and not within the same family, respectively.

sample.include has two primary functions: 1) It can be used to subset the KING output. 2) sample.include can include sample.id not in king; this ensures that all samples will be in the output matrix when reading KING –ibdseg output, which likely does not contain all pairs. When left NULL, the function will determine the list of samples from what is observed in king. It is recommended to use sample.include to ensure all of your samples are included in the output matrix.

thresh sets a threshold for clustering samples such that any pair with an estimated kinship value greater than thresh is in the same cluster. All pairwise estimates within a cluster are kept, even if they are below thresh. All pairwise estimates between clusters are set to 0, creating a sparse block-diagonal matrix. When thresh is NULL, no clustering is done and all samples are returned in one block. This feature is useful when converting KING –ibdseg or KING –robust estimates to be used as a kinship matrix, if you have a lower threshold that you consider ‘related’. This feature should not be used when converting KING –robust estimates to be used as divobj in pcair or pcairPartition, as PC-AiR requires the negative estimates to identify ancestrally divergent pairs.
Value

An object of class ‘Matrix’ with pairwise kinship coefficients by KING --ibdseg or KING --robust for each pair of individuals in the sample. The estimates are on both the upper and lower triangle of the matrix, and the diagonal is arbitrarily set to 0.5. sample.id are set as the column and row names of the matrix.

makeSparseMatrix

Make a sparse matrix from a dense matrix or a table of pairwise values

Description

makeSparseMatrix is used to create a sparse block-diagonal matrix from a dense matrix or a table of pairwise values, using a user-specified threshold for sparsity. An object of class Matrix will be returned. A sparse matrix may be useful for fitting the association test null model with fitNullModel when working with very large sample sizes.
Usage

```r
## S4 method for signature 'data.table'
makeSparseMatrix(x, thresh = NULL, sample.include = NULL, diag.value = NULL, verbose = TRUE)
## S4 method for signature 'data.frame'
makeSparseMatrix(x, thresh = NULL, sample.include = NULL, diag.value = NULL, verbose = TRUE)
## S4 method for signature 'matrix'
makeSparseMatrix(x, thresh = NULL, sample.include = NULL, diag.value = NULL, verbose = TRUE)
## S4 method for signature 'Matrix'
makeSparseMatrix(x, thresh = NULL, sample.include = NULL, diag.value = NULL, verbose = TRUE)
```

Arguments

- **x**: An object to coerce to a sparse matrix. May be of class matrix, Matrix, data.frame, or data.table. When a matrix or Matrix, row and column names should be set to sample.ids; when a data.frame or data.table, should have 3 columns: ID1, ID2, and value.
- **thresh**: Value threshold for clustering samples to make the output matrix sparse block-diagonal. When NULL, no clustering is done. See 'Details'.
- **sample.include**: An optional vector of sample.id indicating all samples that should be included in the output matrix; see 'Details' for usage.
- **diag.value**: When NULL (by Default), values for the diagonal of the output matrix should be provided in x. Setting diag.value to a numeric value will make all values on the diagonal of the output matrix that value.
- **verbose**: A logical indicating whether or not to print status updates to the console; the default is TRUE.

Details

- **sample.include** has two primary functions: 1) It can be used to subset samples provided in x. 2) sample.include can include sample.id not in x; these additional samples will be included in the output matrix, with a value of 0 for all off-diagonal elements, and the value provided by diag.value for the diagonal elements. When left NULL, the function will determine the list of samples from what is observed in x.
- **thresh** sets a threshold for clustering samples such that any pair with a value greater than thresh is in the same cluster. All values within a cluster are kept, even if they are below thresh. All values between clusters are set to 0, creating a sparse, block-diagonal matrix. When thresh is NULL, no clustering is done and all samples are returned in one block. This feature is useful when converting a data.frame of kinship estimates to a matrix.

Value

An object of class 'Matrix'. Samples may be in a different order than in the input x, as samples are sorted by ID or rowname within each block (including within the block of unrelateds).

kingToMatrix and pcrelateToMatrix for functions that use this function.
**Description**

pcair is used to perform a Principal Components Analysis using genome-wide SNP data for the detection of population structure in a sample. Unlike a standard PCA, PC-AiR accounts for sample relatedness (known or cryptic) to provide accurate ancestry inference that is not confounded by family structure.

**Usage**

```r
## S4 method for signature 'gds.class'
pcair(gdsobj, kinobj, divobj,
      kin.thresh = 2^(-11/2), div.thresh = -2^(-11/2),
      unrel.set = NULL,
      sample.include = NULL, snp.include = NULL,
      num.cores = 1L, verbose = TRUE, ...)

## S4 method for signature 'SNPGDSFileClass'
pcair(gdsobj, ...)

## S4 method for signature 'GdsGenotypeReader'
pcair(gdsobj, ...)

## S4 method for signature 'GenotypeData'
pcair(gdsobj, ...)

## S4 method for signature 'SeqVarGDSClass'
pcair(gdsobj, ...)
```

**Arguments**

- `gdsobj` An object providing a connection to a GDS file.
- `kinobj` A symmetric matrix of pairwise kinship coefficients for every pair of individuals in the sample: upper and lower triangles must both be filled; diagonals should be self-kinship or set to a non-missing constant value. This matrix is used for partitioning the sample into the 'unrelated' and 'related' subsets. See 'Details' for how this interacts with `kin.thresh` and `unrel.set`. IDs for each individual must be set as the column names of the matrix. This matrix may also be provided as a GDS object; see 'Details'.
- `divobj` A symmetric matrix of pairwise ancestry divergence measures for every pair of individuals in the sample: upper and lower triangles must both be filled; diagonals should be set to a non-missing constant value. This matrix is used for partitioning the sample into the 'unrelated' and 'related' subsets. See 'Details' for how this interacts with `div.thresh`. IDs for each individual must be set as the column names of the matrix. This matrix may be identical to `kinobj`. This matrix may also be provided as a GDS object; see 'Details'.
- `kin.thresh` Threshold value on `kinobj` used for declaring each pair of individuals as related or unrelated. The default value is $2^{(-11/2)} \approx 0.022$, corresponding to 4th degree relatives. See 'Details' for how this interacts with `kinobj`.
- `div.thresh` Threshold value on `divobj` used for deciding if each pair of individuals is ancestrally divergent. The default value is $-2^{(-11/2)} \approx -0.022$. See 'Details' for how this interacts with `divobj`. 

unrel.set An optional vector of IDs for identifying individuals that are forced into the unrelated subset. See 'Details' for how this interacts with kinobj.

sample.include An optional vector of IDs for selecting samples to consider for either set.
snp.include An optional vector of snp or variant IDs to use in the analysis.
num.cores The number of cores to use.
verbose Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.
...
Additional arguments to pass to snpgdsPCA, such as eigen.cnt to control the number of PCs returned.

Details
The basic premise of PC-AiR is to partition the entire sample of individuals into an ancestry representative 'unrelated subset' and a 'related set', perform standard PCA on the 'unrelated subset', and predict PC values for the 'related subset'.

We recommend using software that accounts for population structure to estimate pairwise kinship coefficients to be used in kinobj. Any pair of individuals with a pairwise kinship greater than kin.thresh will be declared 'related.' Kinship coefficient estimates from the KING-robust software are typically used as measures of ancestry divergence in divobj. Any pair of individuals with a pairwise divergence measure less than div.thresh will be declared ancestrally 'divergent'. Typically, kin.thresh and div.thresh are set to be the amount of error around 0 expected in the estimate for a pair of truly unrelated individuals.

kinobj and divobj may be identical.

There are multiple ways to partition the sample into an ancestry representative 'unrelated subset' and a 'related subset'. If unrel.set = NULL, then the PC-AiR algorithm is used to find an 'optimal' partition (see 'References' for a paper describing the algorithm). If unrel.set is specified, then all individuals with IDs in unrel.set are forced in the 'unrelated subset' and the PC-AiR algorithm is used to partition the rest of the sample; this is especially useful for including reference samples of known ancestry in the 'unrelated subset'.

Value
An object of class 'pcair'. A list including:

vectors A matrix of principal components; each column is a principal component. Sample IDs are provided as rownames. The number of PCs returned can be adjusted by supplying the eigen.cnt argument, which is passed to snpgdsPCA.

values A vector of eigenvalues matching the principal components. These values are determined from the standard PCA run on the 'unrelated subset'.

rels A vector of IDs for individuals in the 'related subset'.
unrels A vector of IDs for individuals in the 'unrelated subset'.

kin.thresh The threshold value used for declaring each pair of individuals as related or unrelated.

div.thresh The threshold value used for determining if each pair of individuals is ancestrally divergent.

sample.id A vector of IDs for the samples used in the analysis.

nsamp The total number of samples in the analysis.

nsnps The total number of SNPs used in the analysis.
pcairPartition

varprop  The variance proportion for each principal component.
call    The function call passed to pcair.
method  A character string. Either "PC-AiR" or "Standard PCA" identifying which method was used for computing principal components. "Standard PCA" is used if no relatives were identified in the sample.

Examples

```r
# file path to GDS file
gdsfile <- system.file("extdata", "HapMap_ASW_MXL_geno.gds", package="GENESIS")
# read in GDS data
HapMap_geno <- gdsfmt::openfn.gds(gdsfile)
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")
# run PC-AiR
mypcair <- pcair(HapMap_geno, kinobj = HapMap_ASW_MXL_KINGmat,
                 divobj = HapMap_ASW_MXL_KINGmat)
gdsfmt::closefn.gds(HapMap_geno)
```

```r
pcairPartition  Partition a sample into an ancestry representative 'unrelated subset' and a 'related subset'
```

Description

pcairPartition is used to partition a sample from a genetic study into an ancestry representative 'unrelated subset' and a 'related subset'. The 'unrelated subset' contains individuals who are all mutually unrelated to each other and representative of the ancestries of all individuals in the sample, and the 'related subset' contains individuals who are related to someone in the 'unrelated subset'.
pcairPartition

Usage

pcairPartition(kinobj, divobj, 
  kin.thresh = 2^(-11/2), div.thresh = -2^(-11/2), 
  unrel.set = NULL, sample.include = NULL, verbose = TRUE)

Arguments

kinobj A symmetric matrix of pairwise kinship coefficients for every pair of individuals in the sample: upper and lower triangles must both be filled; diagonals should be self-kinship or set to a non-missing constant value. This matrix is used for partitioning the sample into the 'unrelated' and 'related' subsets. See 'Details' for how this interacts with kin.thresh and unrel.set. IDs for each individual must be set as the column names of the matrix. This matrix may also be provided as a GDS object; see 'Details'.

divobj A symmetric matrix of pairwise ancestry divergence measures for every pair of individuals in the sample: upper and lower triangles must both be filled; diagonals should be set to a non-missing constant value. This matrix is used for partitioning the sample into the 'unrelated' and 'related' subsets. See 'Details' for how this interacts with div.thresh. IDs for each individual must be set as the column names of the matrix. This matrix may be identical to kinobj. This matrix may also be provided as a GDS object; see 'Details'.

kin.thresh Threshold value on kinobj used for declaring each pair of individuals as related or unrelated. The default value is 2^(-11/2) ~ 0.022, corresponding to 4th degree relatives. See 'Details' for how this interacts with kinobj.

div.thresh Threshold value on divobj used for deciding if each pair of individuals is ancestrally divergent. The default value is -2^(-11/2) ~ -0.022. See 'Details' for how this interacts with divobj.

unrel.set An optional vector of IDs for identifying individuals that are forced into the unrelated subset. See 'Details' for how this interacts with kinobj.

sample.include An optional vector of IDs for selecting samples to consider for either set.

verbose Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details

We recommend using software that accounts for population structure to estimate pairwise kinship coefficients to be used in kinobj. Any pair of individuals with a pairwise kinship greater than kin.thresh will be declared 'related.' Kinship coefficient estimates from the KING-robust software are typically used as measures of ancestry divergence in divobj. Any pair of individuals with a pairwise divergence measure less than div.thresh will be declared ancestrally 'divergent'.

Typically, kin.thresh and div.thresh are set to be the amount of error around 0 expected in the estimate for a pair of truly unrelated individuals. If unrel.set = NULL, the PC-AiR algorithm is used to find an 'optimal' partition (see 'References' for a paper describing the algorithm). If unrel.set and kinobj are both specified, then all individuals with IDs in unrel.set are forced in the 'unrelated subset' and the PC-AiR algorithm is used to partition the rest of the sample; this is especially useful for including reference samples of known ancestry in the 'unrelated subset'.

For large sample sizes, storing both kinobj and divobj in memory may be prohibitive. Both matrices may be stored in GDS files and provided as gds.class objects. pcrelate has an option to save results in GDS format, and we provide utility functions to save KING output in this format as well.

Matrix objects from the Matrix package are also supported.
pcrelate

Value

A list including:

- `rels` A vector of IDs for individuals in the 'related subset'.
- `unrels` A vector of IDs for individuals in the 'unrelated subset'.

Note

`pcairPartition` is called internally in the function `pcair` but may also be used on its own to partition the sample into an ancestry representative 'unrelated' subset and a 'related' subset without performing PCA.

Author(s)

Matthew P. Conomos

- `pcair` which uses this function for finding principal components in the presence of related individuals. `kingToMatrix` for creating a matrix of kinship coefficient estimates or pairwise ancestry divergence measures from KING output text files that can be used as kinobj or divobj. `kin2gds` and `mat2gds` for saving kinship matrices to GDS.

Examples

```r
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")
# partition the sample
part <- pcairPartition(kinobj = HapMap_ASW_MXL_KINGmat,
                        divobj = HapMap_ASW_MXL_KINGmat)
```

pcrelate

PC-Relate: Model-Free Estimation of Recent Genetic Relatedness

Description

pcrelate is used to estimate kinship coefficients, IBD sharing probabilities, and inbreeding coefficients using genome-wide SNP data. PC-Relate accounts for population structure (ancestry) among sample individuals through the use of ancestry representative principal components (PCs) to provide accurate relatedness estimates due only to recent family (pedigree) structure.
Usage

```r
# S4 method for signature 'GenotypeIterator'
pcrelate(gdsobj, pcs, 
scale = c('overall', 'variant', 'none'), 
ibd.probs = TRUE, 
sample.include = NULL, 
training.set = NULL, 
sample.block.size = 5000, 
maf.thresh = 0.01, 
maf.bound.method = c('filter', 'truncate'), 
small.samp.correct = FALSE, 
verbose = TRUE)
# S4 method for signature 'SeqVarIterator'
pcrelate(gdsobj, pcs, 
scale = c('overall', 'variant', 'none'), 
ibd.probs = TRUE, 
sample.include = NULL, 
training.set = NULL, 
sample.block.size = 5000, 
maf.thresh = 0.01, 
maf.bound.method = c('filter', 'truncate'), 
small.samp.correct = FALSE, 
verbose = TRUE)
```

Arguments

- **gdsobj**: An object of class `SeqVarIterator` from the package `SeqVarTools`, or an object of class `GenotypeIterator` from the package `GWASTools`, containing the genotype data for the variants and samples to be used for the analysis.
- **pcs**: A matrix of principal components (PCs) to be used for ancestry adjustment. Each column represents a PC, and each row represents an individual. IDs for each individual must be set as the row names of the matrix.
- **scale**: A character string taking the values 'overall', 'variant', or 'none' indicating how genotype values should be standardized. This should be set to 'overall' (the default) in order to do a PC-Relate analysis; see 'Details' for more information.
- **ibd.probs**: Logical indicator of whether pairwise IBD sharing probabilities (k0, k1, k2) should be estimated; the default is TRUE.
- **sample.include**: A vector of IDs for samples to include in the analysis. If NULL, all samples in gdsobj are included.
- **training.set**: An optional vector of IDs identifying which samples to use for estimation of the ancestry effect when estimating individual-specific allele frequencies. If NULL, all samples in sample.include are used. See 'Details' for more information.
- **sample.block.size**: The number of individuals to read-in/analyze at once; the default value is 5000. See 'Details' for more information.
- **maf.thresh**: Minor allele frequency threshold; if an individual’s estimated individual-specific minor allele frequency at a SNP is less than this value, that individual will either
have that SNP excluded from the analysis or have their estimated individual-specific minor allele frequency truncated to this value, depending on maf.bound.method. The default value is 0.01.

maf.bound.method
How individual-specific minor allele frequency estimates less that maf.thresh are handled. When set to 'filter' (default), SNPs for which an individual's estimated individual-specific minor allele frequency are below maf.thresh are excluded from the analysis for that individual. When set to 'truncate', estimated individual-specific minor allele frequencies below maf.thresh have their value set to maf.thresh.

small.samp.correct
Logical indicator of whether to implement a small sample correction.

verbose
Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details
The basic premise of PC-Relate is to estimate kinship coefficients, IBD sharing probabilities, and inbreeding coefficients that reflect recent family (pedigree) relatedness by conditioning out genetic similarity due to distant population structure (ancestry) with ancestry representative principal components (PCs).

It is important that the PCs used in pcs to adjust for ancestry are representative of ancestry and NOT family structure, so we recommend using PCs calculated with PC-AiR (see: pcair).

In order to perform relatedness estimation, allele frequency estimates are required for centering and scaling genotype values. Individual-specific allele frequencies calculated for each individual at each SNP using the PCs specified in pcs are used. There are multiple choices for how genotype values are scaled. When scale is 'variant', centered genotype values at each SNP are divided by their expected variance under Hardy-Weinberg equilibrium. When scale is 'overall', centered genotype values at all SNPs are divided by the average across all SNPs of their expected variances under Hardy-Weinberg equilibrium; this scaling leads to more stable behavior when using low frequency variants. When scale is 'none', genotype values are only centered and not scaled; this won't provide accurate kinship coefficient estimates but may be useful for other purposes. Set scale to 'overall' to perform a standard PC-Relate analysis; this is the default. If scale is set to 'variant', the estimators are very similar to REAP.

The optional input training.set allows the user to specify which samples are used to estimate the ancestry effect when estimating individual-specific allele frequencies. Ideally, training.set is a set of mutually unrelated individuals. If prior information regarding pedigree structure is available, this can be used to select training.set, or if pcair was used to obtain the PCs, then the individuals in the PC-AiR 'unrelated subset' can be used. If no prior information is available, all individuals should be used.

The sample.block.size can be specified to alleviate memory issues when working with very large data sets. If sample.block.size is smaller than the number of individuals included in the analysis, then individuals will be analyzed in separate blocks. This reduces the memory required for the analysis, but genotype data must be read in multiple times for each block (to analyze all pairs), which increases the number of computations required.

Value
An object of class 'pcrelate'. A list including:

kinBtwn
A data.frame of estimated pairwise kinship coefficients and IBD sharing probabilities (if ibd.probs is TRUE).
kinSelf

A data.frame of estimated inbreeding coefficients.

pcrelateMakeGRM

Creates a Genetic Relationship Matrix (GRM) of Pairwise Kinship Coefficient Estimates from PC-Relate Output

Description

pcrelateMakeGRM is used to create a genetic relationship matrix (GRM) of pairwise kinship coefficient estimates from the output of pcrelate. This function is deprecated; use pcrelateToMatrix with the output of the revised pcrelate.
Usage

pcrelateMakeGRM(pcrelObj, scan.include = NULL, scaleKin = 2)

Arguments

pcrelObj The object containing the output from pcrelate. This could be a list of class pcrelate or an object of class gds.class read into R using the function `openfn.gds` from the gdsfmt package.

scan.include A vector of IDs for samples to be included in the GRM. The default is NULL, which includes all samples in pcrelObj.

scaleKin Specifies a numeric constant to scale each estimated kinship coefficient by in the GRM. The default value is 2.

Details

This function provides a quick and easy way to construct a genetic relationship matrix (GRM) from the output of pcrelate.

pcrelate for the function that performs PC-Relate. pcrelateReadKinship for the function that creates a table of pairwise kinship coefficient and IBD sharing probabilities from the same PC-Relate output file. pcrelateReadInbreed for the function that creates a table of inbreeding coefficient estimates from the same PC-Relate output file.

Description

pcrelateReadInbreed is used to create a table of inbreeding coefficient estimates from the output of pcrelate. This function is deprecated; pcrelate now returns this table as kinSelf.

Usage

pcrelateReadInbreed(pcrelObj, scan.include = NULL, f.thresh = NULL)
pcrelateReadKinship

Arguments

pcrelObj The object containing the output from pcrelate. This could be a list of class pcrelate or an object of class gds.class read into R using the function openfn.gds from the gdsfmt package.

scan.include A vector of IDs for samples to be included in the table. The default is NULL, which includes all samples in pcrelObj.

f.thresh Specifies a minimum value of the estimated inbreeding coefficient to include in the table; i.e. only individuals with an estimated inbreeding coefficient greater than f.thresh will be included in the table. The default is NULL, which includes all individuals.

Details

This function provides an easy way to make a table of estimated inbreeding coefficients.

pcrelateReadKinship

Create a Table of Pairwise Kinship Coefficient and IBD Sharing Probability Estimates from PC-Relate Output

Description

pcrelateReadKinship is used to create a table of pairwise kinship coefficient and IBD sharing probability (k0, k1, k2) estimates from the output of pcrelate. This function is deprecated; pcrelate now returns this table as kinBtwn.

Usage

pcrelateReadKinship(pcrelObj, scan.include = NULL, ibd.probs = TRUE, kin.thresh = NULL)
pcrelateToMatrix

Arguments

- `pcrelobj`: The object containing the output from pcrelate. This could be a list of class `pcrelate` or an object of class `gds.class` read into R using the function `openfn.gds` from the `gdsfmt` package.
- `scan.include`: A vector of IDs for samples to be included in the table. The default is NULL, which includes all samples in `pcrelobj`.
- `ibd.probs`: Logical indicator of whether or not the output in `pcrelobj` has estimates of IBD sharing probabilities.
- `kin.thresh`: Specifies a minimum value of the estimated kinship coefficient to include in the table; i.e. only pairs with an estimated kinship coefficient greater than `kin.thresh` will be included in the table. The default is NULL, which includes all pairs.

Details

This function provides an easy way to make a table of pairwise relatedness estimates.

pcrelateToMatrix

**Description**

pcrelateToMatrix is used to create a genetic relationship matrix (GRM) of pairwise kinship coefficient estimates from the output of pcrelate.

**Usage**

```r
## S4 method for signature 'pcrelate'
pcrelateToMatrix(pcrelobj, sample.include = NULL, thresh = NULL, scaleKin = 2, verbose = TRUE)
```
Arguments

`pcrelobj` The object containing the output from pcrelate. This should be a list of class `pcrelate` containing two data.frames; `kinSelf` with inbreeding coefficient estimates and `kinBtwn` with pairwise kinship coefficient estimates.

`sample.include` A vector of IDs for samples to be included in the GRM. The default is NULL, which includes all samples in `pcrelobj`.

`thresh` Kinship threshold for clustering samples to make the output matrix sparse block-diagonal. This thresholding is done after scaling kinship values by `scaleKin`. When NULL, no clustering is done. See 'Details'.

`scaleKin` Specifies a numeric constant to scale each estimated kinship coefficient by in the GRM. The default value is 2.

`verbose` Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

Details

This function provides a quick and easy way to construct a genetic relationship matrix (GRM) from the output of pcrelate.

`thresh` sets a threshold for clustering samples such that any pair with an estimated kinship value greater than `thresh` is in the same cluster. All pairwise estimates within a cluster are kept, even if they are below `thresh`. All pairwise estimates between clusters are set to 0, creating a sparse, block-diagonal matrix. When `thresh` is NULL, no clustering is done and all samples are returned in one block. This feature may be useful for creating a sparse GRM when running association tests with very large sample sizes. Note that thresholding is done after scaling kinship values by `scaleKin`.

Value

An object of class 'Matrix' with pairwise kinship coefficients.

Author(s)

Matthew P. Conomos

References

See Also

`pcrelate` for the function that performs PC-Relate.
Description

pcrelate is used to estimate kinship coefficients, IBD sharing probabilities, and inbreeding coefficients using genome-wide SNP data. PC-Relate accounts for population structure (ancestry) among sample individuals through the use of ancestry representative principal components (PCs) to provide accurate relatedness estimates due only to recent family (pedigree) structure. Methods for GenotypeData and SeqVarData are deprecated. Use methods for GenotypeIterator and SeqVarIterator instead.

Usage

```r
## S4 method for signature 'GenotypeData'
pcrelate(gdsobj, pcMat = NULL, freq.type = "individual", scale = "overall", ibd.probs = TRUE, scan.include = NULL, training.set = NULL, scan.block.size = 5000, snp.include = NULL, chromosome = NULL, snp.block.size = 10000, MAF = 0.01, write.to.gds = FALSE, gds.prefix = NULL, correct = TRUE, verbose = TRUE)
```

```r
## S4 method for signature 'SeqVarData'
pcrelate(gdsobj, pcMat = NULL, freq.type = "individual", scale = "overall", ibd.probs = TRUE, scan.include = NULL, training.set = NULL, scan.block.size = 5000, snp.include = NULL, chromosome = NULL, snp.block.size = 10000, MAF = 0.01, write.to.gds = FALSE, gds.prefix = NULL, correct = TRUE, verbose = TRUE)
```

Arguments

- `gdsobj` An object of class GenotypeData from the package GWASTools containing the genotype data for SNPs and samples to be used for the analysis. This object can easily be created from a matrix of SNP genotype data, PLINK files, or GDS files. Alternatively, this could be an object of class SeqVarData from the package SeqVarTools containing the genotype data for the sequencing variants and samples to be used for the analysis.

- `pcMat` An optional matrix of principal components (PCs) to be used for ancestry adjustment. Each column represents a PC, and each row represents an individual. IDs for each individual must be set as the row names of the matrix.

- `freq.type` A character string taking the values ‘individual’ or ‘population’ indicating whether genotype values should be adjusted by individual-specific allele frequencies or population average allele frequencies. This should be set to ‘individual’ (the default) in order to do a PC-Relate analysis; see ‘Details’ for more information.

- `scale` A character string taking the values ‘overall’, ‘variant’, or ‘none’ indicating how genotype values should be standardized. This should be set to ‘overall’ (the default) in order to do a PC-Relate analysis; see ‘Details’ for more information.

- `ibd.probs` Logical indicator of whether pairwise IBD sharing probabilities (k0, k1, k2) should be estimated; the default is TRUE.

- `scan.include` A vector of IDs for samples to include in the analysis. If NULL, all samples in genoData are included.
An optional vector of IDs identifying which samples to use for estimation of the ancestry effect when estimating individual-specific allele frequencies. If NULL, all samples in scan.include are used. See 'Details' for more information.

The number of individuals to read-in/analyze at once; the default value is 5000. See 'Details' for more information.

A vector of SNP IDs to include in the analysis. If NULL, see chromosome for further details.

A vector of integers specifying which chromosomes to analyze. This parameter is only considered when snp.include is NULL; if chromosome is also NULL, then all SNPs are included.

The number of SNPs to read-in/analyze at once. The default value is 10000.

Minor allele frequency filter. When freq.type is 'individual', if an individual’s estimated individual-specific minor allele frequency at a SNP is less than this value, that SNP will be excluded from the analysis for that individual. When freq.type is 'population', any SNP with a population minor allele frequency less than this value will be excluded from the analysis. The default value is 0.01.

Logical indicator of whether the output should be written to GDS files. If FALSE (the default), then the output is returned to the R console as expected. See 'Details' for more information.

File path specifying where to save the output when write.to.gds = TRUE. If NULL, the prefix 'tmp' is used. See 'Details' for more information.

Logical indicator of whether to implement a small sample correction.

Logical indicator of whether updates from the function should be printed to the console; the default is TRUE.

The basic premise of PC-Relate is to estimate kinship coefficients, IBD sharing probabilities, and inbreeding coefficients that reflect recent family (pedigree) relatedness by conditioning out genetic similarity due to distant population structure (ancestry) with ancestry representative principal components (PCs). It is important that the PCs used in pcrMat to adjust for ancestry are representative of ancestry and NOT family structure, so we recommend using PCs calculated with PC-AiR. It is important that the order of individuals in the matrix pcrMat matches the order of individuals in genoData.

In order to perform relatedness estimation, allele frequency estimates are required for centering and scaling genotype values. When freq.type is 'individual', individual-specific allele frequencies calculated for each individual at each SNP using the PCs specified in pcrMat are used. When freq.type is 'population', population average allele frequencies calculated at each SNP are used for all individuals. (Note that when freq.type is set to 'population' there is no ancestry adjustment and the relatedness estimates will be confounded with population structure (ancestry)). There are multiple choices for how genotype values are scaled. When scale is 'variant', centered genotype values at each SNP are divided by their expected variance under Hardy-Weinberg equilibrium. When scale is 'overall', centered genotype values at all SNPs are divided by the average across all SNPs of their expected variances under Hardy-Weinberg equilibrium; this scaling leads to more stable behavior when using low frequency variants. When scale is 'none', genotype values are only centered and not scaled; this won’t provide accurate kinship coefficient estimates but may be useful for other purposes. At a particular SNP, the variance used for scaling is either calculated separately for each individual using their individual-specific allele frequencies (when freq.type is 'individual') or once for all individuals using the population average allele frequency (when
freq.type is 'population'). Set freq.type to 'individual' and scale to 'overall' to perform a standard PC-Relate analysis; these are the defaults. If freq.type is set to 'individual' and scale is set to 'variant', the estimators are very similar to REAP. If freq.type is set to 'population' and scale is set to 'variant', the estimators are very similar to EIGENSOFT. The optional input training.set allows the user to specify which samples are used to estimate the ancestry effect when estimating individual-specific allele frequencies (if freq.type is 'individual') or to estimate the population allele frequency (if freq.type is 'population'). Ideally, training.set is a set of mutually unrelated individuals. If prior information regarding pedigree structure is available, this can be used to select training.set, or if pcair was used to obtain the PCs, then the individuals in the PC-AiR 'unrelated subset' can be used. If no prior information is available, all individuals should be used. The scan.block.size can be specified to alleviate memory issues when working with very large data sets. If scan.block.size is smaller than the number of individuals included in the analysis, then individuals will be analyzed in separate blocks. This reduces the memory required for the analysis, but genotype data must be read in multiple times for each block (to analyze all pairs), which increases the number of computations required. NOTE: if individuals are broken up into more than 1 block, write.to.gds must be TRUE (see below). If write.to.gds = TRUE, then the output is written to two GDS files rather than returned to the R console. Use of this option requires the gdsfmt package. The first GDS file, named “<gds.prefix>_freq.gds”, contains the individual-specific allele frequency estimates for each individual at each SNP (when freq.type is 'individual') or the population allele frequency estimates at each SNP (when freq.type is 'population'. The second GDS file, named “<gds.prefix>_pcrelate.gds”, contains the PC-Relate output as described in Value below.

Value

An object of class 'pcrelate'. A list including:

- sample.id: A vector of IDs for samples included in the analysis.
- kinship: A matrix of estimated pairwise kinship coefficients. The order of samples matches sample.id.
- ibd.probs: A matrix of estimated pairwise IBD sharing probabilities; the lower triangle gives k0 (the probability of sharing 0 alleles IBD), the upper triangle gives k2 (the probability of sharing 2 alleles IBD), and the diagonal is missing. The order of samples matches sample.id. This matrix is returned only if ibd.probs = TRUE in the input.
- nsnp: A matrix specifying the the number of SNPs used to estimate the relatedness measures for each pair of individuals. The order of samples matches sample.id.
- kincorrect: A vector specifying the correction factors used for the small sample correction, or NULL.
- k2correct: A vector specifying the correction factors used for the small sample correction, or NULL.
- call: The function call passed to pcrelate.
- method: A character string. Either 'PC-Relate' or 'Unadjusted' identifying which method was used for computing relatedness estimates. 'Unadjusted' is used when pcMat = NULL and corresponds to an assumption of population homogeneity.

Note

The GenotypeData function in the GWASTools package should be used to create the input genoData. Input to the GenotypeData function can easily be created from an R matrix or GDS file. PLINK .bed, .bim, and .fam files can easily be converted to a GDS file with the function snpgdsBED2GDS in
the SNPRelate package. Alternatively, the SeqVarData function in the SeqVarTools package can be used to create the input genodata when working with sequencing data.

Examples

```r
## Not run:
library(GWASTools)
# file path to GDS file
gdsfile <- system.file("extdata", "HapMap_ASW_MXL_geno.gds", package="GENESIS")
# read in GDS data
HapMap_geno <- GdsGenotypeReader(filename = gdsfile)
# create a GenotypeData class object
HapMap_genoData <- GenotypeData(HapMap_geno)
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")
# run PC-AiR
mypcair <- pcair(HapMap_genoData, kinobj = HapMap_ASW_MXL_KINGmat, 
divobj = HapMap_ASW_MXL_KINGmat)
# run PC-Relate
myprel <- pcrelate(HapMap_genoData, pcMat = mypcair$vectors[,1], 
training.set = mypcair$unrels)
close(HapMap_genoData)
## End(Not run)
```

Description

plot.pcair is used to plot pairs of principal components contained in a class 'pcair' object obtained as output from the pcair function.
## Usage

### S3 method for class 'pcair'

```r
plot(x, vx = 1, vy = 2, pch = NULL, col = NULL,
     xlim = NULL, ylim = NULL, main = NULL, sub = NULL,
     xlab = NULL, ylab = NULL, ...)
```

### Arguments

- **x**: An object of class `pcair` obtained as output from the `pcair` function.
- **vx**: An integer indicating which principal component to plot on the x-axis; the default is 1.
- **vy**: An integer indicating which principal component to plot on the y-axis; the default is 2.
- **pch**: Either an integer specifying a symbol or a single character to be used in plotting points. If `NULL`, the default is dots for the 'unrelated subset' and + for the 'related subset'.
- **col**: A specification for the plotting color for points. If `NULL`, the default is black for the 'unrelated subset' and blue for the 'related subset'.
- **xlim**: The range of values shown on the x-axis. If `NULL`, the default shows all points.
- **ylim**: The range of values shown on the y-axis. If `NULL`, the default shows all points.
- **main**: An overall title for the plot. If `NULL`, the default specifies which PC-AiR PCs are plotted.
- **sub**: A sub title for the plot. If `NULL`, the default is none.
- **xlab**: A title for the x-axis. If `NULL`, the default specifies which PC-AiR PC is plotted.
- **ylab**: A title for the y-axis. If `NULL`, the default specifies which PC-AiR PC is plotted.
- **...**: Other parameters to be passed through to plotting functions, (see `par`).

### Details

This function provides a quick and easy way to plot principal components obtained with the function `pcair` to visualize the population structure captured by PC-AiR.

### Value

A figure showing the selected principal components plotted against each other.

### Author(s)

Matthew P. Conomos

**PC-AiR: Principal Components Analysis in Related Samples**

**Description**

Print methods for pcair

**Usage**

```r
## S3 method for class 'pcair'
print(x, ...)
## S3 method for class 'summary.pcair'
print(x, ...)
```

**Arguments**

- `object` An object of class 'pcair', i.e. output from the pcair function.
- `x` An object of class 'pcair', i.e. output from the pcair function.
- `...` Further arguments passed to or from other methods.

**Author(s)**

Matthew P. Conomos

**See Also**

`pcair` for obtaining principal components that capture population structure in the presence of relatedness.
Examples

```r
# file path to GDS file
gdsfile <- system.file("extdata", "HapMap_ASW_MXL_geno.gds", package="GENESIS")
# read in GDS data
HapMap_geno <- gdsfmt::openfn.gds(gdsfile)
# load saved matrix of KING-robust estimates
data("HapMap_ASW_MXL_KINGmat")
# run PC-AiR
mypcair <- pcair(HapMap_geno, kinobj = HapMap_ASW_MXL_KINGmat,
                 divobj = HapMap_ASW_MXL_KINGmat)
print(mypcair)
summary(mypcair)
gdsfmt::closefn.gds(HapMap_geno)
```

---

**sample_annotation_1KG**  
*Annotation for 1000 genomes Phase 3 samples*

**Description**

Annotation for 1000 genomes Phase 3 samples included in the VCF files in "extdata/1KG".

**Usage**

```r
data(sample_annotation_1KG)
```

**Format**

A data.frame with columns:

- sample.id: Sample identifier
- Population: Population of sample
- sex: Sex of sample

**Source**

**References**

**Description**

`varCompCI` provides confidence intervals for the variance component estimates found using `fitNullModel`. The confidence intervals can be found on either the original scale or for the proportion of total variability explained.

**Usage**

```r
varCompCI(nullMMobj, prop = TRUE)
```

**Arguments**

- `nullMMobj`: A null model object returned by `fitNullModel`.
- `prop`: A logical indicator of whether the point estimates and confidence intervals should be returned as the proportion of total variability explained (TRUE) or on the original scale (FALSE).

**Details**

`varCompCI` takes the object returned by `fitNullModel` as its input and returns point estimates and confidence intervals for each of the random effects variance component estimates. If a kinship matrix or genetic relationship matrix (GRM) was included as a random effect in the model fit using `fitNullModel`, then this function can be used to provide a heritability estimate when `prop` is TRUE.

**Value**

`varCompCI` prints a table of point estimates and 95% confidence interval limits for each estimated variance component.

**Author(s)**

Matthew P. Conomos

**See Also**

`fitNullModel` for fitting the mixed model and performing the variance component estimation.
