Package 'Pi'

June 17, 2019

Type Package

Title Leveraging Genetic Evidence to Prioritise Drug Targets at the Gene and Pathway Level

Version 1.12.0

Date 2019-4-17

Author Hai Fang, the ULTRA-DD Consortium, Julian C Knight

Maintainer Hai Fang <hfang@well.ox.ac.uk>

Depends XGR, igraph, dnet, ggplot2, graphics

Imports Matrix, ggbio, GenomicRanges, GenomeInfoDb, supraHex, scales, grDevices, ggrepel, ROCR, randomForest, glmnet, Gviz, lattice, caret, plot3D, stats

Suggests foreach, doParallel, BiocStyle, knitr, rmarkdown, png, GGally, gridExtra, ExpressionAtlas, ggforce, fgsea, pathview, tidyr, dplyr

Description Priority index or Pi is developed as a genomic-led target prioritisation system, with the focus on leveraging human genetic data to prioritise potential drug targets at the gene, pathway and network level. The long term goal is to use such information to enhance early-stage target validation. Based on evidence of disease association from genome-wide association studies (GWAS), this prioritisation system is able to generate evidence to support identification of the specific modulated genes (seed genes) that are responsible for the genetic association signal by utilising knowledge of linkage disequilibrium (co-inherited genetic variants), distance of associated variants from the gene, evidence of independent genetic association with gene expression in disease-relevant tissues, cell types and states, and evidence of physical interactions between disease-associated genetic variants and gene promoters based on genome-wide capture HiC-generated promoter interactomes in primary blood cell types. Seed genes are scored in an integrative way, quantifying the genetic influence. Scored seed genes are subsequently used as baits to rank seed genes plus additional (non-seed) genes; this is achieved by iteratively exploring the global connectivity of a gene interaction network. Genes with the highest priority are further used to identify/prioritise pathways that are significantly enriched with highly prioritised genes. Prioritised genes are also used to identify a gene network interconnecting highly prioritised genes and a minimal number of less prioritised genes (which act as linkers bringing together highly prioritised genes).

R topics documented:

`cTarget` *Definition for S3 class* `cTarget`

Description

`cTarget` has 2 components: priority and predictor.

Usage

```
cTarget(priority, predictor)

## S3 method for class 'cTarget'
print(x, ...)
```

Arguments

`priority`	a data frame
`predictor`	a data frame
`x`	an object of class `cTarget`
`...`	other parameters

Value

an object of S3 class cTarget

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
cTarget(priority, predictor)

## End(Not run)
```

---

dTarget *Definition for S3 class* dTarget

Description

dTarget has 3 components: priority, predictor and metag.

Usage

```
dTarget(priority, predictor, metag)

## S3 method for class 'dTarget'
print(x, ...)
```

Arguments

priority	a data frame
predictor	a data frame
metag	an 'igraph' object
x	an object of class dTarget
...	other parameters

Value

an object of S3 class dTarget

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
```

```
dTarget(priority, predictor, metag)

## End(Not run)
```

---

eGSEA *Definition for S3 class* eGSEA

Description

eGSEA mush have following components: df_summary, leading, full, cross.

Usage

```
eGSEA(df_summary, leading, full, cross)

## S3 method for class 'eGSEA'
print(x, ...)
```

Arguments

df_summary	a data frame
leading	a list
full	a list
cross	a matrix
x	an object of class eGSEA
...	other parameters

Value

an object of S3 class eGSEA

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
eGSEA(df_summary, leading, full, cross)

## End(Not run)
```

eTarget *Definition for S3 class* eTarget

Description

eTarget has 2 components: evidence and metag.

Usage

```
eTarget(evidence, metag)

## S3 method for class 'eTarget'
print(x, ...)
```

Arguments

evidence	a data frame
metag	an 'igraph' object
x	an object of class eTarget
...	other parameters

Value

an object of S3 class eTarget

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
eTarget(evidence, metag)

## End(Not run)
```

pNode *Definition for S3 class* pNode

Description

pNode has 7 components: priority, g, SNP, Gene2SNP, nGenes, eGenes and cGenes.

Usage

```
pNode(priority, g, SNP, Gene2SNP, nGenes, eGenes, cGenes)

## S3 method for class 'pNode'
print(x, ...)
```

Arguments

priority	a data frame
g	an 'igraph' object
SNP	a data frame
Gene2SNP	a data frame
nGenes	a data frame
eGenes	a data frame
cGenes	a data frame
x	an object of class pNode
...	other parameters

Value

an object of S3 class pNode

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
pNode(evidence, metag)

## End(Not run)
```

---

pPerf *Definition for S3 class* pPerf

Description

pPerf mush have following components: PRS, AUROC, Fmax, ROC_perf, PR_perf, Pred_obj.

Usage

```
pPerf(PRS, AUROC, Fmax, ROC_perf, PR_perf, Pred_obj)

## S3 method for class 'pPerf'
print(x, ...)
```

Arguments

PRS	a data frame
AUROC	a scalar
Fmax	a scalar
ROC_perf	a ROCR 'performance' object for ROC curve

PR_perf	a ROCR 'performance' object for PR curve
Pred_obj	a ROCR 'prediction' object for other performance measures
x	an object of class pPerf
...	other parameters

Value

an object of S3 class pPerf

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
pPerf(PRS, AUROC, Fmax, ROC_perf, PR_perf, Pred_obj)

## End(Not run)
```

---

sGS *Definition for S3 class* sGS

Description

sGS mush have following components: GSN, GSP, g.

Usage

```
sGS(GSN, GSP, g)

## S3 method for class 'sGS'
print(x, ...)
```

Arguments

GSN	a vector
GSP	a vector
g	an 'igraph' object
x	an object of class sGS
...	other parameters

Value

an object of S3 class sGS

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
sGS(GSN, GSP, g)

## End(Not run)
```

---

sTarget *Definition for S3 class* sTarget

Description

sTarget mush have following components: priority, predictor, performance, importance, evidence.

Usage

```
sTarget(priority, predictor, performance, importance, evidence)

## S3 method for class 'sTarget'
print(x, ...)
```

Arguments

priority	a data frame
predictor	a data frame
performance	a data frame
importance	a data frame
evidence	an 'eTarget' object
x	an object of class sTarget
...	other parameters

Value

an object of S3 class sTarget

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
sTarget(priority, predictor, performance, importance, evidence)

## End(Not run)
```

xContour *Function to visualise a numeric matrix as a contour plot*

Description

xContour is supposed to visualise a numeric matrix as a contour plot.

Usage

```
xContour(data, main = "", xlab = "", ylab = "", key = "",
nlevels = 50,
colormap = c("darkblue-lightblue-lightyellow-darkorange", "bwr", "jet",
"gbr", "wyr", "br", "yr", "rainbow", "wb"), highlight = c("none",
"min", "max"), highlight.col = "white", x.label.cex = 0.95,
x.label.srt = 30, signature = FALSE, ...)
```

Arguments

data	a numeric matrix for the contour plot
main	an overall title for the plot
xlab	a title for the x axis. If specified, it will override 'names(dimnames(data))[1]'
ylab	a title for the y axis. If specified, it will override 'names(dimnames(data))[2]'
key	a title for the key plot (on the right)
nlevels	the number of levels to partition the input matrix values. The same level has the same color mapped to
colormap	short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), and "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta). Alternatively, any hyphen-separated HTML color names, e.g. "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names
highlight	how to highlight the point. It can be 'none' for no highlight (by default), 'min' for highlighting the point with the minimum value of the matrix, and 'max' for highlighting the point with the maximum value of the matrix
highlight.col	the highlight colors
x.label.cex	the x-axis label size
x.label.srt	the x-axis label angle (in degree from horizontal)
signature	a logical to indicate whether the signature is assigned to the plot caption. By default, it sets FALSE
...	additional graphic parameters. For most parameters, please refer to http://stat.ethz.ch/R-manual/R-devel/library/graphics/html/filled.contour.html

Value

invisible

Note

none

See Also

xContour

Examples

```
x <- y <- seq(-4*pi, 4*pi, len=10)
r <- sqrt(outer(x^2, y^2, "+"))
data <- cos(r^2)*exp(-r/(2*pi))
xContour(data)
#xContour(data, signature=TRUE)
```

---

xCorrelation *Function to calculate and visualise correlation*

Description

xCorrelation is supposed to calculate and visualise correlation between a data frame and a named vector (or a list of named vectors).

Usage

```
xCorrelation(df, list_vec, method = c("pearson", "spearman"),
p.type = c("nominal", "empirical"), seed = 825, nperm = 2000,
p.adjust.method = c("BH", "BY", "bonferroni", "holm", "hochberg",
"hommel"), plot = FALSE, plot.smooth = c(NA, "lm", "loess"))
```

Arguments

df	a data frame with two columns ('name' and 'value')
list_vec	a named vector containing numeric values. Alternatively it can be a list of named vectors
method	the method used to calcualte correlation. It can be 'pearson' for Pearson's correlation or 'spearman' for Spearman rank correlation
p.type	the type of the p-value calcualted. It can be 'nominal' for nominal p-value or 'empirical' for empirical p-value
seed	an integer specifying the seed
nperm	the number of random permutations
p.adjust.method	the method used to adjust p-values. It can be one of "BH", "BY", "bonferroni", "holm", "hochberg" and "hommel". The first two methods "BH" (widely used) and "BY" control the false discovery rate (FDR: the expected proportion of false discoveries amongst the rejected hypotheses); the last four methods "bonferroni", "holm", "hochberg" and "hommel" are designed to give strong control of the family-wise error rate (FWER). Notes: FDR is a less stringent condition than FWER
plot	logical to indicate whether scatter plot is drawn
plot.smooth	the smooth method for the scatter plot. It can be NA (depending on correlation type), "lm" for the linear line or 'loess' for the loess curve

Value

a list with three componets:

- df_summary: a data frame of n x 5, where n is the number of named vectors, and the 5 columns are "name", "num" (i.e. number of data points used for calculation), "cor" (i.e. correlation), "pval" (i.e. p-value), "fdr"
- ls_gp_curve: NULL if the plot is not drawn; otherwise, a list of 'ggplot' objects for scatter plot together with an estimated curve
- ls_gp_pdf: NULL if the plot is not drawn; otherwise, a list of 'ggplot' objects for pdf plot for null distribution of correlation together with a vertical line for observed correlation

Note

none

xGSEAbarplot *Function to visualise GSEA results using a barplot*

Description

xGSEAbarplot is supposed to visualise GSEA results using a barplot. It returns an object of class "ggplot".

Usage

```
xGSEAbarplot(eGSEA, top_num = 10, displayBy = c("nes", "adjp", "fdr",
"pvalue"), FDR.cutoff = 0.05, bar.label = TRUE, bar.label.size = 3,
bar.color = "lightyellow-orange", bar.width = 0.8,
wrap.width = NULL, font.family = "sans", signature = TRUE)
```

Arguments

eGSEA	an object of class "eGSEA"
top_num	the number of the top terms (sorted according to FDR or adjusted p-values). If it is 'auto', only the significant terms (see below FDR.cutoff) will be displayed
displayBy	which statistics will be used for displaying. It can be "nes" for normalised enrichment score (by default), "adjp" or "fdr" for adjusted p value (or FDR), "pvalue" for p value
FDR.cutoff	FDR cutoff used to declare the significant terms. By default, it is set to 0.05. This option only works when setting top_num (see above) is 'auto'
bar.label	logical to indicate whether to label each bar with FDR. By default, it sets to true for bar labelling
bar.label.size	an integer specifying the bar labelling text size. By default, it sets to 3
bar.color	either NULL or fill color names ('lightyellow-orange' by default)
bar.width	bar width. By default, 80 data
wrap.width	a positive integer specifying wrap width of name
font.family	the font family for texts
signature	logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph

Value

an object of class "ggplot"

Note

none

print(bp)
#dev.off()
```

```
## End(Not run)
```

---

xGSEAconciser *Function to make GSEA results conciser by removing redundant terms*

Description

xGSEAconciser is supposed to make GSEA results conciser by removing redundant terms. A redundant term (called 'B') is claimed if its overlapped part (A&B) with a more significant term (called 'A') meets both criteria: 1) |A&B| > 0.9*|B|; and 2) |A&B| > 0.5*|A|.

Usage

```
xGSEAconciser(eGSEA, cutoff = c(0.9, 0.5), verbose = TRUE)
```

Arguments

eGSEA	an object of class "eGSEA"
cutoff	a cutoff vector used to remove redundant terms. By default, it has the first element 0.9 and the second element 0.5. It means, for a term (less significant; called 'B'), if there is a more significant term (called 'A'), their overlapped members cover at least 90 this term B will be defined as redundant and thus being removed
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to false for no display

Value

an object of class "eGSEA", after redundant terms being removed.

Note

none

See Also

xPierGSEA

Examples

```
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
eGSEA_concise <- xGSEAconciser(eGSEA)

## End(Not run)
```

xGSEAdotplot *Function to visualise GSEA results using dot plot*

Description

xGSEAdotplot is supposed to visualise GSEA results using dot plot. It returns an object of class "ggplot" or a list of "ggplot" objects.

Usage

```
xGSEAdotplot(eGSEA, top = 1, colormap = "lightblue-darkblue",
zlim = NULL, ncolors = 64, xlab = NULL, title = NULL,
subtitle = c("leading", "enrichment", "both", "none"),
clab = "Pi rating", x.scale = c("normal", "sqrt", "log"),
peak = TRUE, peak.color = "red", leading = FALSE,
leading.size = 2, leading.color = "black", leading.alpha = 0.6,
leading.padding = 0.2, leading.arrow = 0.01, leading.force = 0.01,
leading.query = NULL, leading.query.only = FALSE,
leading.edge.only = FALSE, compact = FALSE, font.family = "sans",
signature = TRUE, ...)
```

Arguments

eGSEA	an object of class "eGSEA"
top	the number of the top enrichments to be visualised. Alternatively, the gene set names can be queried
colormap	short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), and "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta). Alternatively, any hyphen-separated HTML color names, e.g. "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names
zlim	the minimum and maximum z values for which colors should be plotted
ncolors	the number of colors specified over the colormap
xlab	the label for x-axis. If NULL, it is 'Target ranks'
title	the title. If NULL, it is term name followed by the number of its annotations
subtitle	the subtitle. It can be used to show 'leading' info, 'enrichment' info or 'both'
clab	the label for colorbar. By default, it is '5-star ratings'
x.scale	how to transform the x scale. It can be "normal" for no transformation, "sqrt" for square root transformation, and "log" for log-based transformation
peak	logical to indicate whether the peak location is shown
peak.color	the peak color
leading	logical to indicate whether the leading targets are texted. Alterntively, leading can be numeric to restict the top targets displayed

leading.size	the size of leading targets' texts. It only works when the parameter 'leading' is enabled
leading.color	the label color of leading targets' texts
leading.alpha	the 0-1 value specifying transparency of leading targets' texts
leading.padding	the padding around the leading targets' texts
leading.arrow	the arrow pointing to the leading targets
leading.force	the repelling force between leading targets' texts
leading.query	which genes in query will be labelled. By default, it sets to NULL meaning all genes will be displayed. If labels in query can not be found, then all will be displayed
leading.query.only	logical to indicate whether only genes in query will be displayed. By default, it sets to FALSE. It only works when labels in query are enabled/found
leading.edge.only	logical to indicate whether only the leading edge will be shown. By default, it sets to FALSE
compact	logical to indicate whether the compact/void theme is used. If TRUE, axes and legend info will be hidden
font.family	the font family for texts
signature	logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph
...	additional paramters associated with ggrepel::geom_text_repel. If queried, it has high priority (eg, color='darkred',size=2,alpha=0.6,fontface='bold')

Value

an object of class "ggplot" or a list of "ggplot" objects.

Note

none

```

`xGSsimulator` *Function to simulate gold standard negatives (GSN) given gold standard positives (GSP) and a gene network*

Description

`xGSsimulator` is supposed to simulate gold standard negatives (GSN) given gold standard positives (GSP) and an input gene network. GSN targets are those after excluding GSP targets and their 1-order (by default) neighbors in the gene network.

Usage

```
xGSsimulator(GSP, population = NULL, network = c("STRING_medium",
"STRING_low", "STRING_high", "STRING_highest", "PCommonsUN_high",
"PCommonsUN_medium")[c(1, 6)], network.customised = NULL,
neighbor.order = 1, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

`GSP`	a vector containing Gold Standard Positives (GSP)
`population`	a vector containing population space in which gold standard negatives (GSN) will be considered. By default, it is NULL, meaning genes in the network will be used instead
`network`	the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathways Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). By default, "STRING_medium" and "PCommonsUN_medium" are used
`network.customised`	an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network

neighbor.order	an integer giving the order of the neighborhood. By default, it is 1-order neighborhood
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details

Value

a list with following components:

- GSN: a vector containing simulated GSN
- GSP: a vector containing GSP after considering the population space
- g: an "igraph" object

Note

If multiple graphs are provided, they will be unionised for use.

xMLcaret *Function to integrate predictor matrix in a supervised manner via machine learning algorithms using caret.*

Description

xMLcaret is supposed to integrate predictor matrix in a supervised manner via machine learning algorithms using caret. The caret package streamlines model building and performance evaluation. It requires three inputs: 1) Gold Standard Positive (GSP) targets; 2) Gold Standard Negative (GSN) targets; 3) a predictor matrix containing genes in rows and predictors in columns, with their predictive scores inside it. It returns an object of class 'sTarget'.

Usage

```
xMLcaret(list_pNode = NULL, df_predictor = NULL, GSP, GSN,
method = c("gbm", "svmRadial", "rda", "knn", "pls", "nnet", "rf",
"myrf", "cforest", "glmnet", "glm", "bayesglm", "LogitBoost",
"xgbLinear", "xgbTree"), nfold = 3, nrepeat = 10, seed = 825,
aggregateBy = c("none", "logistic", "Ztransform", "fishers",
"orderStatistic"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

`list_pNode`	a list of "pNode" objects or a "pNode" object
`df_predictor`	a data frame containing genes (in rows) and predictors (in columns), with their predictive scores inside it. This data frame must has gene symbols as row names
`GSP`	a vector containing Gold Standard Positive (GSP)
`GSN`	a vector containing Gold Standard Negative (GSN)
`method`	machine learning method. It can be one of "gbm" for Gradient Boosting Machine (GBM), "svmRadial" for Support Vector Machines with Radial Basis Function Kernel (SVM), "rda" for Regularized Discriminant Analysis (RDA), "knn" for k-nearest neighbor (KNN), "pls" for Partial Least Squares (PLS), "nnet" for Neural Network (NNET), "rf" for Random Forest (RF), "myrf" for customised Random Forest (RF), "cforest" for Conditional Inference Random Forest, "glmnet" for glmnet, "glm" for Generalized Linear Model (GLM), "bayesglm" for Bayesian Generalized Linear Model (BGLM), "LogitBoost" for Boosted Logistic Regression (BLR), "xgbLinear" for eXtreme Gradient Boosting as linear booster (XGBL), "xgbTree" for eXtreme Gradient Boosting as tree booster (XGBT)
`nfold`	an integer specifying the number of folds for cross validataion. Per fold creates balanced splits of the data preserving the overall distribution for each class (GSP and GSN), therefore generating balanced cross-vallidation train sets and testing sets. By default, it is 3 meaning 3-fold cross validation
`nrepeat`	an integer specifying the number of repeats for cross validataion. By default, it is 10 indicating the cross-validation repeated 10 times
`seed`	an integer specifying the seed
`aggregateBy`	the aggregate method used to aggregate results from repeated cross validataion. It can be either "none" for no aggregration (meaning the best model based on all data used for cross validation is used), or "orderStatistic" for the method based on the order statistics of p-values, or "fishers" for Fisher's method, "Ztransform" for Z-transform method, "logistic" for the logistic method. Without loss of generality, the Z-transform method does well in problems where evidence against the combined null is spread widely (equal footings) or when the total evidence is weak; Fisher's method does best in problems where the evidence is concentrated in a relatively small fraction of the individual tests or when the evidence is at least moderately strong; the logistic method provides a compromise between these two. Notably, the aggregate methods 'Ztransform' and 'logistic' are preferred here
`verbose`	logical to indicate whether the messages will be displayed in the screen. By default, it sets to TRUE for display
`RData.location`	the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "sTarget", a list with following components:

- `model`: an object of class "train" as a best model
- `ls_model`: a list of best models from repeated cross-validation
- `priority`: a data frame of n X 5 containing gene priority information, where n is the number of genes in the input data frame, and the 5 columns are "GS" (either 'GSP', or 'GSN', or 'Putative'), "name" (gene names), "rank" (priority rank), "rating" (5-star priority score/rating), and "description" (gene description)
- `predictor`: a data frame, which is the same as the input data frame but inserting two additional columns ('GS' in the first column, 'name' in the second column)
- `performance`: a data frame of 1+nPredictor X 2 containing the supervised/predictor performance info, where nPredictor is the number of predictors, two columns are "ROC" (AUC values) and "Fmax" (F-max values)
- `performance_cv`: a data frame of nfold*nrepeat X 2 containing the repeated cross-validation performance, where two columns are "ROC" (AUC values) and "Fmax" (F-max values)
- `importance`: a data frame of nPredictor X 1 containing the predictor importance info
- gp: a ggplot object for the ROC curve
- gp_cv: a ggplot object for the ROC curves from repeated cross-validation
- `evidence`: an object of the class "eTarget", a list with following components "evidence" and "metag"
- `list_pNode`: a list of "pNode" objects

Note

It will depend on whether a package "caret" and its suggested packages have been installed. It can be installed via: `BiocManager::install(c("caret","e1071","gbm","kernlab","klaR","pls","nnet","randomFor`

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
sTarget <- xMLcaret(df_prediction, GSP, GSN, method="myrf")

## End(Not run)
```

`xMLcompare` *Function to visualise cross-validation performance against tuning parameters*

Description

`xMLcompare` is supposed to visualise cross-validation performance against tuning parameters.

Usage

```
xMLcompare(list_ML, metric = c("ROC", "Sens", "Spec"), xlab = NA,
xlimits = c(0.5, 1), font.family = "sans")
```

Arguments

list_ML	a list of class "train" or "train.formula" objects (resulting from caret::train)
metric	the performance metric to plot. It can be one of 'ROC', 'Sens' (Sensitivity) and 'Spec' (Specificity)
xlab	a title for the x axis
xlimits	the limit for the x axis
font.family	the font family for texts

Value

an object of class "ggplot"

Note

none

See Also

xMLcompare

Examples

```
## Not run:
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
gp <- xMLcompare(ls_ML, xlimits=c(0.5,1))

## End(Not run)
```

---

xMLdensity *Function to visualise machine learning results using density plot*

Description

xMLdensity is supposed to visualise machine learning results using density plot. It returns an object of class "ggplot".

Usage

```
xMLdensity(xTarget, displayBy = c("All", "GS", "GSN", "GSP", "NEW"),
x.scale = c("sqrt", "normal"), font.family = "sans",
signature = TRUE)
```

Arguments

xTarget	an object of class "xTarget" or "dTarget" (with the component 'pPerf')
displayBy	which targets will be used for displaying. It can be one of "GS" for gold standard targets, "GSN" for gold standard negatives, "GSP" for gold standard positives, "NEW" for putative/new targets (non-GS), "All" for all targets (by default)
x.scale	how to transform the x scale. It can be "normal" for no transformation, and "sqrt" for square root transformation (by default)
font.family	the font family for texts
signature	logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph

Value

an object of class "ggplot"

Note

none

See Also

xMLrandomforest

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
gp <- xMLdensity(xTarget, displayBy="All")
gp

## End(Not run)
```

---

xMLdotplot *Function to visualise machine learning results using dot plot*

Description

xMLdotplot is supposed to visualise machine learning results using dot plot. It returns an object of class "ggplot".

Usage

```
xMLdotplot(sTarget, displayBy = c("importance2fold", "roc2fold",
"fmax2fold", "importance_accurancy", "importance_gini", "ROC", "Fmax"),
ML.included = T, font.family = "sans", signature = TRUE)
```

Arguments

sTarget	an object of class "sTarget"
displayBy	which statistics will be used for displaying. It can be either statistics across folds ("importance2fold" for predictor importance, "roc2fold" for AUC in ROC, "fmax2fold" for F-max in Precision-Recall curve) or overall statistics ("importance_accurancy" for predictor importance measured by accuracy decrease, "importance_gini" for predictor importance measured by Gini decrease, "ROC" for AUC in ROC, "Fmax" for F-max in Precision-Recall curve)
ML.included	logical to indicate whether to use ML results
font.family	the font family for texts
signature	logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph

Value

an object of class "ggplot"

Note

none

See Also

xMLrandomforest

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
gp <- xMLdotplot(sTarget, displayBy="importance_accurancy")
gp

## End(Not run)
```

---

xMLfeatureplot *Function to visualise/assess features used for machine learning*

Description

xMLfeatureplot is supposed to visualise/assess features used for machine learning. Visualisation can be made using either boxplot or dot plot for AUC and F-max. It returns an object of class "ggplot" for AUC and F-max, and an object of class "trellis" for boxplot.

Usage

```
xMLfeatureplot(df_predictor, GSP, GSN, displayBy = c("boxplot", "ROC",
"Fmax"), font.family = "sans", ...)
```

Arguments

df_predictor	a data frame containing genes (in rows) and predictors (in columns), with their predictive scores inside it. This data frame must has gene symbols as row names
GSP	a vector containing Gold Standard Positive (GSP)
GSN	a vector containing Gold Standard Negative (GSN)
displayBy	which statistics will be used for displaying. It can be either "boxplot" for features themselves, "ROC" for AUC in ROC, "Fmax" for F-max in Precision-Recall curve)
font.family	the font family for texts
...	additional parameters. Please refer to 'lattice::bwplot' for the complete list.

Value

an object of class "ggplot" for AUC and F-max, and an object of class "trellis" for boxplot

Note

none

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
gp <- xMLfeatureplot(df_predictor, GSP, GSN, displayBy="ROC")

## End(Not run)
```

---

xMLglmnet *Function to integrate predictor matrix in a supervised manner via machine learning algorithm glmnet.*

Description

xMLglmnet is supposed to integrate predictor matrix in a supervised manner via machine learning algorithm glmnet. It requires three inputs: 1) Gold Standard Positive (GSP) targets; 2) Gold Standard Negative (GSN) targets; 3) a predictor matrix containing genes in rows and predictors in columns, with their predictive scores inside it. It returns an object of class 'pTarget'.

Usage

```
xMLglmnet(df_predictor, GSP, GSN, family = c("binomial", "gaussian"),
type.measure = c("auc", "mse"), nfold = 3, alphas = seq(0, 1, 0.1),
standardize = TRUE, lower.limits = -Inf, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

df_predictor	a data frame containing genes (in rows) and predictors (in columns), with their predictive scores inside it. This data frame must has gene symbols as row names
GSP	a vector containing Gold Standard Positive (GSP)
GSN	a vector containing Gold Standard Negative (GSN)
family	response family type. It can be one of "binomial" for two-class logistic model or "gaussian" for gaussian model
type.measure	loss to use for cross-validation. It can be one of "auc" for two-class logistic model, "mse" for the deviation from the fitted mean to the response using gaussian model
nfold	an integer specifying the number of folds for cross validataion
alphas	a vector specifying a range of alphas. Alpha is an elasticnet mixing parameter, with 0<=alpha<=1. By default, seq(0,1,by-0.1)
standardize	logical specifying whether to standardise the predictor. If yes (by default), the predictor standardised prior to fitting the model. The coefficients are always returned on the original scale
lower.limits	vector of lower limits for each coefficient (by default, '-Inf'; all should be non-positive). A single value provided will apply to every coefficient
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to TRUE for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details
...	additional parameters. Please refer to 'glmnet::cv.glmnet' for the complete list.

Value

an object of class "pTarget", a list with following components:

- model: an object of class "cv.glmnet" as a best model
- priority: a data frame of nGene X 5 containing gene priority information, where nGene is the number of genes in the input data frame, and the 5 columns are "GS" (either 'GSP', or 'GSN', or 'NEW'), "name" (gene names), "rank" (ranks of the priority scores), "priority" (priority score; rescaled into the 5-star ratings), and "description" (gene description)
- predictor: a data frame, which is the same as the input data frame but inserting an additional column 'GS' in the first column
- cvm2alpha: a data frame of nAlpha X 2 containing mean cross-validated error, where nAlpha is the number of alpha and the two columns are "min" (lambda.min) and "1se" (lambda.1se)
- nonzero2alpha: a data frame of nAlpha X 2 containing the number of non-zero coefficients, where nAlpha is the number of alpha and the two columns are "min" (lambda.min) and "1se" (lambda.1se)
- importance: a data frame of nPredictor X 1 containing the predictor importance/coefficient info
- performance: a data frame of 1+nPredictor X 2 containing the supervised/predictor performance info predictor importance info, where nPredictor is the number of predictors, two columns are "ROC" (AUC values) and "Fmax" (F-max values)
- gp: a ggplot object for the ROC curve
- call: the call that produced this result

Note

none

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
pTarget <- xMLglmnet(df_prediction, GSP, GSN)

## End(Not run)
```

---

xMLparameters — *Function to visualise cross-validation performance against tuning parameters*

Description

xMLparameters is supposed to visualise cross-validation performance against tuning parameters.

Usage

```
xMLparameters(data, nD = c("auto", "1D", "2D", "3D"), contour = TRUE,
main = "Repeated cross-validation", xlab = NA, ylab = NA,
zlab = NA, clab = "AUC (repeated CV)", nlevels = 50,
colormap = c("lightblue-lightyellow-darkorange-darkred", "bwr", "jet",
"gbr", "wyr", "br", "yr", "rainbow", "wb"), highlight = TRUE,
x.label.cex = 0.8, x.label.srt = 30, theta.3D = 40, phi.3D = 25)
```

Arguments

data	an object of the class "train" or "train.formula" (resulting from caret::train) used for 1D or 2D visualisation. Alternatively, it can be a data frame used for 2D or 3D visualisation
nD	an integer specifying the dimension of the visualisation. It can be one of '1D', '2D' and '3D' and 'auto' (if input data is a "train" object)
contour	logical to indicate whether coutour plot should be also included
main	a title for the plot
xlab	a title for the x axis
ylab	a title for the y axis
zlab	a title for the z axis
clab	a title for the colorbar
nlevels	the number of levels to partition the input matrix values. The same level has the same color mapped to

colormap	short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), and "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta). Alternatively, any hyphen-separated HTML color names, e.g. "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names
highlight	logical whether to highlight the point with the maximum value
x.label.cex	the x-axis label size
x.label.srt	the x-axis label angle (in degree from horizontal)
theta.3D	the azimuthal direction. By default, it is 40
phi.3D	the colatitude direction. By default, it is 20

Value

invisible

Note

none

xMLrandomforest *Function to integrate predictor matrix in a supervised manner via machine learning algorithm random forest.*

Description

xMLrandomforest is supposed to integrate predictor matrix in a supervised manner via machine learning algorithm random forest. It requires three inputs: 1) Gold Standard Positive (GSP) targets; 2) Gold Standard Negative (GSN) targets; 3) a predictor matrix containing genes in rows and predictors in columns, with their predictive scores inside it. It returns an object of class 'sTarget'.

Usage

```
xMLrandomforest(list_pNode = NULL, df_predictor = NULL, GSP, GSN,
nfold = 3, nrepeat = 10, seed = 825, mtry = NULL, ntree = 1000,
fold.aggregateBy = c("logistic", "Ztransform", "fishers",
"orderStatistic"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

list_pNode	a list of "pNode" objects or a "pNode" object
df_predictor	a data frame containing genes (in rows) and predictors (in columns), with their predictive scores inside it. This data frame must has gene symbols as row names
GSP	a vector containing Gold Standard Positive (GSP)
GSN	a vector containing Gold Standard Negative (GSN)
nfold	an integer specifying the number of folds for cross validataion. Per fold creates balanced splits of the data preserving the overall distribution for each class (GSP and GSN), therefore generating balanced cross-vallidation train sets and testing sets. By default, it is 3 meaning 3-fold cross validation
nrepeat	an integer specifying the number of repeats for cross validataion. By default, it is 10 indicating the cross-validation repeated 10 times
seed	an integer specifying the seed
mtry	an integer specifying the number of predictors randomly sampled as candidates at each split. If NULL, it will be tuned by 'randomForest::tuneRF', with starting value as sqrt(p) where p is the number of predictors. The minimum value is 3
ntree	an integer specifying the number of trees to grow. By default, it sets to 2000
fold.aggregateBy	the aggregate method used to aggregate results from k-fold cross validataion. It can be either "orderStatistic" for the method based on the order statistics of p-values, or "fishers" for Fisher's method, "Ztransform" for Z-transform method, "logistic" for the logistic method. Without loss of generality, the Z-transform method does well in problems where evidence against the combined null is spread widely (equal footings) or when the total evidence is weak; Fisher's method does best in problems where the evidence is concentrated in a relatively small fraction of the individual tests or when the evidence is at least moderately strong; the logistic method provides a compromise between these two. Notably, the aggregate methods 'Ztransform' and 'logistic' are preferred here
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to TRUE for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details
...	additional parameters. Please refer to 'randomForest::randomForest' for the complete list.

Value

an object of class "sTarget", a list with following components:

- model: a list of models, results from per-fold train set

- `priority`: a data frame of nGene X 5 containing gene priority information, where nGene is the number of genes in the input data frame, and the 5 columns are "GS" (either 'GSP', or 'GSN', or 'NEW'), "name" (gene names), "rank" (priority rank), "rating" (the 5-star priority score/rating), and "description" (gene description)
- `predictor`: a data frame, which is the same as the input data frame but inserting an additional column 'GS' in the first column
- `pred2fold`: a list of data frame, results from per-fold test set
- `prob2fold`: a data frame of nGene X 2+nfold containing the probability of being GSP, where nGene is the number of genes in the input data frame, nfold is the number of folds for cross validataion, and the first two columns are "GS" (either 'GSP', or 'GSN', or 'NEW'), "name" (gene names), and the rest columns storing the per-fold probability of being GSP
- `importance2fold`: a data frame of nPredictor X 4+nfold containing the predictor importance info per fold, where nPredictor is the number of predictors, nfold is the number of folds for cross validataion, and the first 4 columns are "median" (the median of the importance across folds), "mad" (the median of absolute deviation of the importance across folds), "min" (the minimum of the importance across folds), "max" (the maximum of the importance across folds), and the rest columns storing the per-fold importance
- `roc2fold`: a data frame of 1+nPredictor X 4+nfold containing the supervised/predictor ROC info (AUC values), where nPredictor is the number of predictors, nfold is the number of folds for cross validataion, and the first 4 columns are "median" (the median of the AUC values across folds), "mad" (the median of absolute deviation of the AUC values across folds), "min" (the minimum of the AUC values across folds), "max" (the maximum of the AUC values across folds), and the rest columns storing the per-fold AUC values
- `fmax2fold`: a data frame of 1+nPredictor X 4+nfold containing the supervised/predictor PR info (F-max values), where nPredictor is the number of predictors, nfold is the number of folds for cross validataion, and the first 4 columns are "median" (the median of the F-max values across folds), "mad" (the median of absolute deviation of the F-max values across folds), "min" (the minimum of the F-max values across folds), "max" (the maximum of the F-max values across folds), and the rest columns storing the per-fold F-max values
- `importance`: a data frame of nPredictor X 2 containing the predictor importance info, where nPredictor is the number of predictors, two columns for two types ("MeanDecreaseAccuracy" and "MeanDecreaseGini") of predictor importance measures. "MeanDecreaseAccuracy" sees how worse the model performs without each predictor (a high decrease in accuracy would be expected for very informative predictors), while "MeanDecreaseGini" measures how pure the nodes are at the end of the tree (a high score means the predictor was important if each predictor is taken out)
- `performance`: a data frame of 1+nPredictor X 2 containing the supervised/predictor performance info predictor performance info, where nPredictor is the number of predictors, two columns are "ROC" (AUC values) and "Fmax" (F-max values)
- `evidence`: an object of the class "eTarget", a list with following components "evidence" and "metag"
- `list_pNode`: a list of "pNode" objects

Note

none

Examples

```
## Not run:
```

```
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
sTarget <- xMLrandomforest(df_prediction, GSP, GSN)

## End(Not run)
```

---

xMLrename *Function to rename predictors used in machine learning*

Description

xMLrename is supposed to rename predictors used in machine learning. It returns an object of class "sTarget".

Usage

```
xMLrename(sTarget, old_names, new_names)
```

Arguments

sTarget	an object of class "sTarget"
old_names	a vector for the original names of predictors to be renamed
new_names	a vector for the new names

Value

an object of class "sTarget"

Note

none

## End(Not run)
```

`xMLzoom` *Function to visualise machine learning results using zoom plot*

Description

`xMLzoom` is supposed to visualise machine learning results using zoom plot. It returns an object of class "ggplot".

Usage

```
xMLzoom(xTarget, top = 20, top.label.type = c("box", "text"),
top.label.size = 3, top.label.query = NULL, point.shape = 3,
font.family = "sans", signature = TRUE)
```

Arguments

`xTarget`	an object of class "sTarget" or "dTarget" (with the component 'pPerf')
`top`	the number of the top targets to be labelled/highlighted
`top.label.type`	how to label the top targets. It can be "box" drawing a box around the labels , and "text" for the text only
`top.label.size`	the highlight label size

top.label.query
: which top genes in query will be labelled. By default, it sets to NULL meaning all top genes will be displayed. If labels in query can not be found, then none will be displayed

point.shape
: an integer specifying point shapes. By default, it is 3 for cross. For details, please refere to http://sape.inf.usi.ch/quick-reference/ggplot2/shape

font.family
: the font family for texts

signature
: logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE

Value

an object of class "ggplot"

xPier *Function to do prioritisation through random walk techniques*

Description

xPier is supposed to prioritise nodes given an input graph and a list of seed nodes. It implements Random Walk with Restart (RWR) and calculates the affinity score of all nodes in the graph to the seeds. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPier(seeds, g, seeds.inclusive = TRUE, normalise = c("laplacian",
"row", "column", "none"), restart = 0.7,
normalise.affinity.matrix = c("none", "quantile"), parallel = TRUE,
multicores = NULL, verbose = TRUE)
```

Arguments

seeds	a named input vector containing a list of seed nodes. For this named vector, the element names are seed/node names (e.g. gene symbols), the element (non-zero) values used to weight the relative importance of seeds. Alternatively, it can be a matrix or data frame with two columns: 1st column for seed/node names, 2nd column for the weight values
g	an object of class "igraph" to represent network. It can be a weighted graph with the node attribute 'weight'
seeds.inclusive	logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk
normalise	the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'
restart	the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)
normalise.affinity.matrix	the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles
parallel	logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed
multicores	an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

Value

an object of class "pNode", a list with following components:

- priority: a matrix of nNode X 5 containing node priority information, where nNode is the number of nodes in the input graph, and the 5 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores)
- g: an input "igraph" object

Note

The input graph will treat as an unweighted graph if there is no 'weight' edge attribute associated with

xPierABF *Function to prioritise genes based on seed eGenes identified through ABF integrating GWAS and eQTL summary data*

Description

xPierABF is supposed to prioritise genes based on seed eGenes identified through ABF integrating GWAS and eQTL summary data. To prioritise genes, it first conducts colocalisation analysis through Wakefield's Approximate Bayes Factor (ABF) integrating GWAS and eQTL summary data to identify and score seed genes (that is, eGenes weighted by posterior probability of the SNP being causal for both GWAS and eQTL traits). It implements Random Walk with Restart (RWR) and calculates the affinity score of all nodes in the graph to the seeds. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPierABF(data, eqtl = c("CD14", "LPS2", "LPS24", "IFN", "Bcell", "NK",
"Neutrophil", "CD4", "CD8", "Blood", "Monocyte", "shared_CD14",
"shared_LPS2", "shared_LPS24", "shared_IFN"), prior.eqtl = 1e-04,
prior.gwas = 1e-04, prior.both = 1e-05, cutoff.H4 = 0.8,
cutoff.pgwas = 1e-05, network = c("STRING_highest", "STRING_high",
"STRING_medium", "STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high", "PCommonsDN_medium", "PCommonsDN_Reactome",
```

```
"PCommonsDN_KEGG", "PCommonsDN_HumanCyc", "PCommonsDN_PID",
"PCommonsDN_PANTHER", "PCommonsDN_ReconX", "PCommonsDN_TRANSFAC",
"PCommonsDN_PhosphoSite", "PCommonsDN_CTD", "KEGG", "KEGG_metabolism",
"KEGG_genetic", "KEGG_environmental", "KEGG_cellular",
"KEGG_organismal",
"KEGG_disease"), STRING.only = c(NA, "neighborhood_score",
"fusion_score", "cooccurence_score", "coexpression_score",
"experimental_score", "database_score", "textmining_score")[1],
weighted = FALSE, network.customised = NULL,
seeds.inclusive = TRUE, normalise = c("laplacian", "row", "column",
"none"), restart = 0.7, normalise.affinity.matrix = c("none",
"quantile"), parallel = TRUE, multicores = NULL, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a data frame storing GWAS summary data with following required columns 'snp', 'effect' (the effect allele assessed), 'other' (other allele), 'b' (effect size for the allele assessed; log(odds ratio) for a case-control study), 'se' (standard error), 'p' (p-value)
eqtl	context-specific eQTL summary data. It can be one of "Bcell","Blood","CD14","CD4","CD8","IFN",
prior.eqtl	the prior probability an eQTL associated with the eQTL trait. The default value is 1e-4
prior.gwas	the prior probability an SNP associated with the GWAS trait. The default value is 1e-4
prior.both	the prior probability an eQTL/SNP associated with both eQTL/GWAS traits. The default value is 1e-5
cutoff.H4	the H4 cutoff used to define eGenes. This cutoff is based on the posterior probabilities of H4 - one shared causal variant. The default value is 0.8
cutoff.pgwas	the GWAS p-value cutoff that must be met to consider SNPs. The default value is 1e-5
network	the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathways Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addtion to pooled version of pathways from all

data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex
Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix`
the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

multicores	an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details

Value

an object of class "pNode", a list with following components:

- priority: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 5 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object
- evidence: a data frame storing evidence
- call: the call that produced this result

Note

The input graph will treat as an unweighted graph if there is no 'weight' edge attribute associated with

## End(Not run)
```

xPierABFheatmap *Function to visualise ABF evidence using heatmap*

Description

xPierABFheatmap is supposed to visualise ABF evidence using heatmap. It returns an object of class "ggplot".

Usage

```
xPierABFheatmap(data, xTarget, type = c("Gene", "Gene_SNP"),
colormap = "steelblue-lightyellow-orange", zlim = c(-0.5, 0.5))
```

Arguments

data	an input vector containing gene symbols
xTarget	a "dTarget" or "sTarget" object with the componet 'list_pNode' related to 'eGene' predictors. Alternatively, it can be a data frame with columns ('context','mode','probeID','Symbol','g
type	the type of the heatmap. It can be "Gene" (gene-centric heatmap) or "Gene_SNP" (heatmap for the gene-snp pair)
colormap	short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), and "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta). Alternatively, any hyphen-separated HTML color names, e.g. "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names
zlim	the minimum and maximum z values for which colors should be plotted

Value

an object of class "ggplot" appended with 'mat' (the matrix colored by 'b_ABF') and 'df' (a data frame with columns 'priority','code','context','mode','ProbeID','Symbol','gene_cse','snps','snp_cse','A1','A2','b_GW

xPierAnno *Function to prioritise seed genes only from a list of pNode objects using annotation data*

Description

xPierAnno is supposed to prioritise seed genes only from a list of pNode objects using annotation data. To prioritise genes, it first extracts seed genes from a list of pNode objects and then scores seed genes using annotation data (or something similar). It implements Random Walk with Restart (RWR) and calculates the affinity score of all nodes in the graph to the seeds. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPierAnno(data, list_pNode, network = c("STRING_highest",
"STRING_high",
"STRING_medium", "STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high", "PCommonsDN_medium", "PCommonsDN_Reactome",
"PCommonsDN_KEGG", "PCommonsDN_HumanCyc", "PCommonsDN_PID",
"PCommonsDN_PANTHER", "PCommonsDN_ReconX", "PCommonsDN_TRANSFAC",
"PCommonsDN_PhosphoSite", "PCommonsDN_CTD", "KEGG", "KEGG_metabolism",
"KEGG_genetic", "KEGG_environmental", "KEGG_cellular",
"KEGG_organismal",
"KEGG_disease"), STRING.only = c(NA, "neighborhood_score",
"fusion_score", "cooccurence_score", "coexpression_score",
"experimental_score", "database_score", "textmining_score")[1],
weighted = FALSE, network.customised = NULL,
seeds.inclusive = TRUE, normalise = c("laplacian", "row", "column",
"none"), restart = 0.7, normalise.affinity.matrix = c("none",
"quantile"), parallel = TRUE, multicores = NULL, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a data frame with two columns: 1st column for seed/node names, 2nd column for the weight values. It intends to store annotation data or something similar
list_pNode	a list of "pNode" objects or a "pNode" object. Alternatively, it is NULL, meaning no restrictioin
network	the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathways Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for

interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addtion to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex
Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix`
: the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel`
: logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores`
: an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose`
: logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`RData.location`
: the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "pNode", a list with following components:

- `priority`: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 5 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object
- `call`: the call that produced this result

Note

The input graph will treat as an unweighted graph if there is no 'weight' edge attribute associated with

write.table(pNode_anno$priority, file="Genes_priority.Anno.txt",
sep="\t", row.names=FALSE)

## End(Not run)
```

`xPierCor` *Function to calculate correlation between prioritised genes and user-defined external data*

Description

`xPierCor` is supposed to calculate correlation between prioritised genes and user-defined external data.

Usage

```
xPierCor(pNode, list_vec, method = c("pearson", "spearman"),
pvalue.type = c("nominal", "empirical"), seed = 825, nperm = 2000,
p.adjust.method = c("BH", "BY", "bonferroni", "holm", "hochberg",
"hommel"), plot = FALSE)
```

Arguments

`pNode`	an object of class "pNode" (or "sTarget" or "dTarget"). Alternatively, it can be a data frame with two columns ('name' and 'priority')
`list_vec`	a named vector containing numeric values for genes (gene symbols). Alternatively it can be a list of named vectors
`method`	the method used to calcualte correlation. It can be 'pearson' for Pearson's correlation or 'spearman' for Spearman rank correlation
`pvalue.type`	the type of the p-value calcualted. It can be 'nominal' for nominal p-value or 'empirical' for empirical p-value
`seed`	an integer specifying the seed

nperm	the number of random permutations
p.adjust.method	the method used to adjust p-values. It can be one of "BH", "BY", "bonferroni", "holm", "hochberg" and "hommel". The first two methods "BH" (widely used) and "BY" control the false discovery rate (FDR: the expected proportion of false discoveries amongst the rejected hypotheses); the last four methods "bonferroni", "holm", "hochberg" and "hommel" are designed to give strong control of the family-wise error rate (FWER). Notes: FDR is a less stringent condition than FWER
plot	logical to indicate whether scatter plot is drawn

Value

a list with two componets:

- df_summary: a data frame of n x 4, where n is the number of named vectors, and the 4 columns are "name", "cor" (i.e. "correlation"), "pval" (i.e. p-value), "fdr"
- ls_gp: NULL if the plot is not drawn; otherwise, a list of 'ggplot' objects

Note

none

## End(Not run)
```

`xPierCross` *Function to extract priority matrix from a list of dTarget/sTarget objects*

Description

`xPierCross` is supposed to extract priority matrix from a list of dTarget objects. Also supported is the aggregation of priority matrix (similar to the meta-analysis) generating the priority results; we view this functionality as the cross mode of the prioritisation.

Usage

```
xPierCross(list_xTarget, displayBy = c("rating", "rank", "pvalue",
"fdr"), combineBy = c("intersect", "union"), aggregateBy = c("none",
"fishers", "logistic", "Ztransform", "orderStatistic"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

`list_xTarget`	a list of "dTarget"/"sTarget" objects or a "dTarget"/"sTarget" object
`displayBy`	which priority will be extracted. It can be "rating" for priority score/rating (by default), "rank" for priority rank, "pvalue" for priority p-value, "fdr" for priority fdr
`combineBy`	how to resolve nodes/targets from a list of "dTarget"/"sTarget" objects. It can be "intersect" for intersecting nodes (by default), "union" for unionising nodes
`aggregateBy`	the aggregate method used. It can be either "none" for no aggregation, or "orderStatistic" for the method based on the order statistics of p-values, "fishers" for Fisher's method, "Ztransform" for Z-transform method, "logistic" for the logistic method. Without loss of generality, the Z-transform method does well in problems where evidence against the combined null is spread widely (equal footings) or when the total evidence is weak; Fisher's method does best in problems where the evidence is concentrated in a relatively small fraction of the individual tests or when the evidence is at least moderately strong; the logistic method provides a compromise between these two. Notably, the aggregate methods 'fishers' and 'logistic' are preferred here
`verbose`	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
`RData.location`	the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

If aggregateBy is 'none' (by default), a data frame containing priority matrix, with each column/disease for either priority score/rating, or priorty rank or priority p-value. If aggregateBy is not 'none', an object of the class "cTarget", a list with following components:

- priority: a data frame of nGene X 6 containing gene priority (aggregated) information, where nGene is the number of genes, and the 6 columns are "name" (gene names), "rank" (ranks of the priority scores), "pvalue" (the aggregated p-value, converted from empirical cumulative distribution of the probability of being GSP), "fdr" (fdr adjusted from the aggregated p-value), "priority" (-log10(pvalue) but rescaled into the 5-star ratings), "description" (gene description)
- disease: a data frame containing disease matrix, with each column/disease for either priority score, or priorty rank or priority p-value

xPierEvidence *Function to extract evidence from a list of pNode objects*

Description

xPierEvidence is supposed to extract evidence from a list of pNode objects, in terms of seed genes under genetic influence.

Usage

```
xPierEvidence(list_pNode, target.query = NULL, verbose = TRUE)
```

Arguments

list_pNode	a list of "pNode" objects or a "pNode" object
target.query	which gene is in query. If NULL, all genes will be queried
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

Value

a data frame of nPair X 5 containing Gene-SNP pair info per context, where the 6 columns are "Gene" (seed genes), "SNP" (dbSNP), "Score" (an SNP's genetic influential score on a seed gene), "Context" (predictors), "Flag" (indicative of Lead SNPs or LD SNPs), and "Pval" (the SNP p-value)

xPierGenes *Function to prioritise genes from an input network and the weight info imposed on its nodes*

Description

xPierGenes is supposed to prioritise genes given an input graph and a list of seed nodes. It implements Random Walk with Restart (RWR) and calculates the affinity score of all nodes in the graph to the seeds. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPierGenes(data, network = c("STRING_highest", "STRING_high",
"STRING_medium", "STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high", "PCommonsDN_medium", "PCommonsDN_Reactome",
"PCommonsDN_KEGG", "PCommonsDN_HumanCyc", "PCommonsDN_PID",
"PCommonsDN_PANTHER", "PCommonsDN_ReconX", "PCommonsDN_TRANSFAC",
"PCommonsDN_PhosphoSite", "PCommonsDN_CTD", "KEGG", "KEGG_metabolism",
"KEGG_genetic", "KEGG_environmental", "KEGG_cellular",
"KEGG_organismal",
"KEGG_disease", "REACTOME"), STRING.only = c(NA, "neighborhood_score",
"fusion_score", "cooccurence_score", "coexpression_score",
"experimental_score", "database_score", "textmining_score")[1],
weighted = FALSE, network.customised = NULL,
seeds.inclusive = TRUE, normalise = c("laplacian", "row", "column",
```

```
"none"), restart = 0.7, normalise.affinity.matrix = c("none",
"quantile"), parallel = TRUE, multicores = NULL, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a named input vector containing a list of seed nodes (ie gene symbols). For this named vector, the element names are seed/node names (e.g. gene symbols), the element (non-zero) values used to weight the relative importance of seeds. Alternatively, it can be a matrix or data frame with two columns: 1st column for seed/node names, 2nd column for the weight values
network	the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways
STRING.only	the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised` an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive` logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix` the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores` an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose` logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`RData.location` the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "pNode", a list with following components:

- `priority`: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 5 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object

Note

The input graph will treat as an unweighted graph if there is no 'weight' edge attribute associated with

xPierGRs *Function to prioritise genes given a list of genomic regions*

Description

xPierGRs is supposed to prioritise genes given a list of genomic regions with or without the significance level. To prioritise genes, it first defines and scores genes crosslinking to an input list of genomic regions (GR). With seed genes and their scores, it then uses Random Walk with Restart (RWR) to calculate the affinity score of all nodes in the input graph to the seed genes. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPierGRs(data, significance.threshold = NULL, score.cap = NULL,
build.conversion = c(NA, "hg38.to.hg19", "hg18.to.hg19"),
crosslink = c("genehancer", "PCHiC_combined", "GTEx_V6p_combined",
"nearby"), crosslink.customised = NULL, cdf.function = c("original",
"empirical"), scoring.scheme = c("max", "sum", "sequential"),
nearby.distance.max = 50000, nearby.decay.kernel = c("rapid", "slow",
"linear", "constant"), nearby.decay.exponent = 2,
```

```
network = c("STRING_highest", "STRING_high", "STRING_medium",
"STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high",
"PCommonsDN_medium", "PCommonsDN_Reactome", "PCommonsDN_KEGG",
"PCommonsDN_HumanCyc", "PCommonsDN_PID", "PCommonsDN_PANTHER",
"PCommonsDN_ReconX", "PCommonsDN_TRANSFAC", "PCommonsDN_PhosphoSite",
"PCommonsDN_CTD", "KEGG", "KEGG_metabolism", "KEGG_genetic",
"KEGG_environmental", "KEGG_cellular", "KEGG_organismal",
"KEGG_disease",
"REACTOME"), STRING.only = c(NA, "neighborhood_score", "fusion_score",
"cooccurence_score", "coexpression_score", "experimental_score",
"database_score", "textmining_score")[1], weighted = FALSE,
network.customised = NULL, seeds.inclusive = TRUE,
normalise = c("laplacian", "row", "column", "none"), restart = 0.7,
normalise.affinity.matrix = c("none", "quantile"), parallel = TRUE,
multicores = NULL, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a named input vector containing the significance level for genomic regions (GR). For this named vector, the element names are GR, in the format of 'chrN:start-end', where N is either 1-22 or X, start (or end) is genomic positional number; for example, 'chr1:13-20', the element values for the significance level (measured as p-value or fdr). Alternatively, it can be a matrix or data frame with two columns: 1st column for GR, 2nd column for the significance level. Also supported is the input with GR only (without the significance level)
significance.threshold	the given significance threshold. By default, it is set to NULL, meaning there is no constraint on the significance level when transforming the significance level of GR into scores. If given, those GR below this are considered significant and thus scored positively. Instead, those above this are considered insignificant and thus receive no score
score.cap	the maximum score being capped. By default, it is set to NULL, meaning that no capping is applied
build.conversion	the conversion from one genome build to another. The conversions supported are "hg38.to.hg19" and "hg18.to.hg19". By default it is NA (no need to do so)
crosslink	the built-in crosslink info with a score quantifying the link of a GR to a gene. See xGR2xGenes for details
crosslink.customised	the crosslink info with a score quantifying the link of a GR to a gene. A user-input matrix or data frame with 4 columns: 1st column for genomic regions (formatted as "chr:start-end", genome build 19), 2nd column for Genes, 3rd for crosslink score (crosslinking a genomic region to a gene, such as -log10 significance level), and 4th for contexts (optional; if nor provided, it will be added as 'C'). Alternatively, it can be a file containing these 4 columns. Required, otherwise it will return NULL
cdf.function	a character specifying how to transform the input crosslink score. It can be one of 'original' (no such transformation), and 'empirical' for looking at empirical Cumulative Distribution Function (cdf; as such it is converted into pvalue-like values [0,1])

`scoring.scheme` the method used to calculate seed gene scores under a set of GR (also over Contexts if many). It can be one of "sum" for adding up, "max" for the maximum, and "sequential" for the sequential weighting. The sequential weighting is done via: $\sum_{i=1} \frac{R_i}{i}$, where R_i is the i^{th} rank (in a descreasing order)

`nearby.distance.max`
the maximum distance between genes and GR. Only those genes no far way from this distance will be considered as seed genes. This parameter will influence the distance-component weights calculated for nearby GR per gene

`nearby.decay.kernel`
a character specifying a decay kernel function. It can be one of 'slow' for slow decay, 'linear' for linear decay, and 'rapid' for rapid decay. If no distance weight is used, please select 'constant'

`nearby.decay.exponent`
a numeric specifying a decay exponent. By default, it sets to 2

`network` the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex

Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix`
the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores` an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose` logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`RData.location` the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "pNode", a list with following components:

- `priority`: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 6 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)

- g: an input "igraph" object
- mSeed: a list with following components 'GR', 'Gene' and 'Link'

xPierGSEA *Function to prioritise pathways based on GSEA analysis of prioritised genes*

Description

xPierGSEA is supposed to prioritise pathways given prioritised genes and the ontology in query. It is done via gene set enrichment analysis (GSEA). It returns an object of class "eGSEA".

Usage

```
xPierGSEA(pNode, priority.top = NULL, ontology = c("GOBP", "GOMF",
"GOCC", "PS", "PS2", "SF", "Pfam", "DO", "HPPA", "HPMI", "HPCM",
"HPMA",
"MP", "EF", "MsigdbH", "MsigdbC1", "MsigdbC2CGP", "MsigdbC2CPall",
"MsigdbC2CP", "MsigdbC2KEGG", "MsigdbC2REACTOME", "MsigdbC2BIOCARTA",
"MsigdbC3TFT", "MsigdbC3MIR", "MsigdbC4CGN", "MsigdbC4CM",
"MsigdbC5BP",
"MsigdbC5MF", "MsigdbC5CC", "MsigdbC6", "MsigdbC7", "DGIdb", "GTExV4",
"GTExV6p", "GTExV7", "CreedsDisease", "CreedsDiseaseUP",
"CreedsDiseaseDN", "CreedsDrug", "CreedsDrugUP", "CreedsDrugDN",
"CreedsGene", "CreedsGeneUP", "CreedsGeneDN", "KEGG",
"KEGGmetabolism", "KEGGgenetic", "KEGGenvironmental", "KEGGcellular",
"KEGGorganismal", "KEGGdisease"), customised.genesets = NULL,
size.range = c(10, 500), p.adjust.method = c("BH", "BY",
"bonferroni", "holm", "hochberg", "hommel"), path.mode = c("all_paths",
"shortest_paths", "all_shortest_paths"), weight = 1, seed = 825,
nperm = 2000, fast = TRUE, verbose = TRUE, silent = FALSE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget"). Alternatively, it can be a data frame with two columns ('priority' and 'rank')
priority.top	the number of the top targets used for GSEA. By default, it is NULL meaning all targets are used
ontology	the ontology supported currently. It can be "GOBP" for Gene Ontology Biological Process, "GOMF" for Gene Ontology Molecular Function, "GOCC" for Gene Ontology Cellular Component, "PS" for phylostratific age information, "PS2" for the collapsed PS version (inferred ancestors being collapsed into one with the known taxonomy information), "SF" for SCOP domain superfamilies, "Pfam" for Pfam domain families, "DO" for Disease Ontology, "HPPA" for Human Phenotype Phenotypic Abnormality, "HPMI" for Human Phenotype Mode of Inheritance, "HPCM" for Human Phenotype Clinical Modifier, "HPMA" for Human Phenotype Mortality Aging, "MP" for Mammalian Phenotype, "EF" for Experimental Factor Ontology (used to annotate GWAS Catalog genes), Drug-Gene Interaction database ("DGIdb") for drugable categories, tissue-specific eQTL-containing genes from GTEx ("GTExV4", "GTExV6p" and "GTExV7"), crowd extracted expression of differential signatures from CREEDS ("CreedsDisease", "CreedsDiseaseUP", "CreedsDiseaseDN", "CreedsDrug", "CreedsDrugUP", "CreedsDrugDN", "CreedsGene", "CreedsGeneUP" and "CreedsGeneDN"), KEGG pathways (including 'KEGG' for all, 'KEGGmetabolism' for 'Metabolism' pathways, 'KEGGgenetic' for 'Genetic Information Processing' pathways, 'KEGGenvironmental' for 'Environmental Information Processing' pathways, 'KEGGcellular' for 'Cellular Processes' pathways, 'KEGGorganismal' for 'Organismal Systems' pathways, and 'KEGGdisease' for 'Human Diseases' pathways), and the molecular signatures database (Msigdb, including "MsigdbH", "MsigdbC1", "MsigdbC2CGP", "MsigdbC2CPall", "MsigdbC2CP", "MsigdbC2KEGG", "MsigdbC2REACTOME "MsigdbC2BIOCARTA", "MsigdbC3TFT", "MsigdbC3MIR", "MsigdbC4CGN", "MsigdbC4CM", "MsigdbC5BP", "MsigdbC5MF", "MsigdbC5CC", "MsigdbC6", "MsigdbC7")

`customised.genesets`
: a list each containing gene symbols. By default, it is NULL. If the list provided, it will overtake the previous parameter "ontology"

`size.range`
: the minimum and maximum size of members of each term in consideration. By default, it sets to a minimum of 10 but no more than 500

`p.adjust.method`
: the method used to adjust p-values. It can be one of "BH", "BY", "bonferroni", "holm", "hochberg" and "hommel". The first two methods "BH" (widely used) and "BY" control the false discovery rate (FDR: the expected proportion of false discoveries amongst the rejected hypotheses); the last four methods "bonferroni", "holm", "hochberg" and "hommel" are designed to give strong control of the family-wise error rate (FWER). Notes: FDR is a less stringent condition than FWER

`path.mode`
: the mode of paths induced by vertices/nodes with input annotation data. It can be "all_paths" for all possible paths to the root, "shortest_paths" for only one path to the root (for each node in query), "all_shortest_paths" for all shortest paths to the root (i.e. for each node, find all shortest paths with the equal lengths)

`weight`
: an integer specifying score weight. It can be "0" for unweighted (an equivalent to Kolmogorov-Smirnov, only considering the rank), "1" for weighted by input gene score (by default), and "2" for over-weighted, and so on

`seed`
: an integer specifying the seed

`nperm`
: the number of random permutations. For each permutation, gene-score associations will be permutated so that permutation of gene-term associations is realised

`fast`
: logical to indicate whether to fast calculate GSEA resulting. By default, it sets to true, but not necessarily does so. It will depend on whether the package "fgsea" has been installed

`verbose`
: logical to indicate whether the messages will be displayed in the screen. By default, it sets to true

`silent`
: logical to indicate whether the messages will be silent completely. By default, it sets to false. If true, verbose will be forced to be false

`RData.location`
: the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "eGSEA", a list with following components:

- `df_summary`: a data frame of nTerm x 9 containing gene set enrichment analysis result, where nTerm is the number of terms/genesets, and the 9 columns are "setID" (i.e. "Term ID"), "name" (i.e. "Term Name"), "nAnno" (i.e. number in members annotated by a term), "nLead" (i.e. number in members as leading genes), "peak" (i.e. the rank at peak), "total" (i.e. the total number of genes analysed), "es" (i.e. enrichment score), "nes" (i.e. normalised enrichment score; enrichment score but after being normalised by gene set size), "pvalue" (i.e. nominal p value), "adjp" (i.e. adjusted p value; p value but after being adjusted for multiple comparisons), "distance" (i.e. term distance or metadata)
- `leading`: a list of gene sets, each storing leading gene info (i.e. the named vector with names for gene symbols and elements for priority rank). Always, gene sets are identified by "setID"
- `full`: a list of gene sets, each storing full info on gene set enrichment analysis result (i.e. a data frame of nGene x 6, where nGene is the number of genes, and the 6 columns are "GeneID", "Rank" for priority rank, "Score" for priority score, "RES" for running enrichment

score, "Hits" for gene set hits info with 1 for gene hit, 2 for leading gene hit, 3 for the point defining leading genes, 0 for no hit), and "Symbol" for gene symbols. Always, gene sets are identified by "setID"

- `cross`: a matrix of nTerm X nTerm, with an on-diagnal cell for the leading genes observed in an individaul term, and off-diagnal cell for the overlapped leading genes shared between two terms

Note

none

xPierKEGG *Function to visualise prioritised genes in terms of a KEGG pathway*

Description

xPierKEGG is supposed to visualise prioritised genes in terms of a KEGG pathway. It returns an object of class "igraph".

Usage

```
xPierKEGG(xTarget, vis = c("net", "evidence", "pathview"),
hsa = "hsa04621", priority.top = NULL, incoming.neighbor.order = 1,
nodes_query = NULL, largest.comp = TRUE, pathview.filename = NULL,
pathview.filetype = c("png", "pdf"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

xTarget	an object of class "dTarget" or "sTarget"
vis	the type of visualisation for a KEGG pathway. It can be one of "net" (visualising the network with nodes colored by priority score; by default), "evidence" for visualising the network with nodes as pie charts, and "pathview" for using the package "pathview"
hsa	the identity of KEGG pathway in query. The full list of pathways in human can be found at http://www.genome.jp/kegg-bin/show_organism?menu_type=pathway_maps&org=hsa. For example, 'hsa04621' for 'NOD-like receptor signaling pathway', where the prefix 'hsa' can be ignored
priority.top	the number of the top targets. By default, it is NULL meaning no such restriction
incoming.neighbor.order	an integer giving the order of the incoming neighborhood. By default, it is 1-order incoming neighborhood
nodes_query	which gene in query will be visualised. It (if not null) has the high priority over nodes selected by 'priority.top' and 'incoming.neighbor.order' above
largest.comp	logical to indicate whether the largest component is only retained. By default, it sets to true for the largest component being left
pathview.filename	the file name saved using the package "pathview". By default, it is NULL meaning "hsa.Pi"
pathview.filetype	the file format saved using the package "pathview". It can be "png" or "pdf"
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details
...	additional graphic parameters. If the type of visualisation is 'net', see xVisNet; if the visualisation type is 'evidence', see xVisEvidence

Value

a subgraph, an object of class "igraph".

Note

If vis is 'pathview', it will depend on whether a package "pathview" has been installed. It can be installed via: `BiocManager::install("pathview")`.

xPierManhattan *Function to visualise prioritised genes using manhattan plot*

Description

xPierManhattan is supposed to visualise prioritised genes using manhattan plot. Genes with the top priority are highlighed. It returns an object of class "ggplot".

Usage

```
xPierManhattan(pNode, color = c("darkred", "darkgreen"), top = 50,
top.label.type = c("box", "text"), top.label.size = 2,
top.label.col = "darkblue", top.label.query = NULL,
label.query.only = FALSE, chromosome.only = TRUE,
y.scale = c("normal", "sqrt", "log"), y.lab = NULL,
GR.Gene = c("UCSC_knownGene", "UCSC_knownCanonical"),
font.family = "sans", signature = TRUE, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget")
color	a character vector for colors to alternate chromosome colorings. If NULL, ggplot2 default colors will be used. If a single character is provided, it can be "jet" (jet colormap) or "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta)
top	the number of the top targets to be labelled/highlighted
top.label.type	how to label the top targets. It can be "box" drawing a box around the labels , and "text" for the text only
top.label.size	the highlight label size
top.label.col	the highlight label color

`top.label.query`
: which top genes in query will be labelled. By default, it sets to NULL meaning all top genes will be displayed. If labels in query can not be found, then all will be displayed

`label.query.only`
: logical to indicate whether only genes in query will be displayed. By default, it sets to FALSE. It only works when labels in query are enabled/found

`chromosome.only`
: logical to indicate whether only genes from input data will be displayed. By default, it sets to TRUE

`y.scale`
: how to transform the y scale. It can be "normal" for no transformation, "sqrt" for square root transformation, and "log" for log-based transformation

`y.lab`
: the y labelling. If NULL (by default), it shows the column of input data

`GR.Gene`
: the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location"

`font.family`
: the font family for texts

`signature`
: logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE

`verbose`
: logical to indicate whether the messages will be displayed in the screen. By default, it sets to false for no display

`RData.location`
: the characters to tell the location of built-in RData files. See `xRDataLoader` for details

`...`
: additional paramters associated with ggrepel::geom_text_repel

Value

an object of class "ggplot", appended by an GR object called 'gr'

Note

none

```

`xPierMatrix` *Function to extract priority or evidence matrix from a list of pNode objects*

Description

`xPierMatrix` is supposed to extract priority or evidence matrix from a list of pNode objects. Also supported is the aggregation of priority matrix (similar to the meta-analysis) generating the priority results; we view this functionality as the discovery mode of the prioritisation.

Usage

```
xPierMatrix(list_pNode, displayBy = c("score", "rank", "weight",
```

```
"pvalue", "evidence"), combineBy = c("union", "intersect"),
aggregateBy = c("none", "fishers", "logistic", "Ztransform",
"orderStatistic"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

list_pNode	a list of "pNode" objects or a "pNode" object
displayBy	which priority will be extracted. It can be "score" for priority score/rating (by default), "rank" for priority rank, "weight" for seed weight, "pvalue" for priority p-value, "evidence" for the evidence (seed info)
combineBy	how to resolve nodes/targets from a list of "pNode" objects. It can be "intersect" for intersecting nodes (by default), "union" for unionising nodes
aggregateBy	the aggregate method used. It can be either "none" for no aggregation, or "orderStatistic" for the method based on the order statistics of p-values, "fishers" for Fisher's method, "Ztransform" for Z-transform method, "logistic" for the logistic method. Without loss of generality, the Z-transform method does well in problems where evidence against the combined null is spread widely (equal footings) or when the total evidence is weak; Fisher's method does best in problems where the evidence is concentrated in a relatively small fraction of the individual tests or when the evidence is at least moderately strong; the logistic method provides a compromise between these two. Notably, the aggregate methods 'fishers' and 'logistic' are preferred here
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details

Value

If displayBy is 'evidence', an object of the class "eTarget", a list with following components:

- evidence: a data frame of nGene X 6 containing gene evidence information, where nGene is the number of genes, and the 7 columns are seed info including "Overall" for the total number of different types of seeds, followed by details on individual type of seeds (that is, "dGene", "pGene", "fGene", "nGene", "eGene", "cGene")
- metag: an "igraph" object

Otherwise (if displayBy is not 'evidence'), if aggregateBy is 'none' (by default), a data frame containing priority matrix, with each column/predictor for either priority score, or priorty rank or priority p-value. If aggregateBy is not 'none', an object of the class "dTarget", a list with following components:

- priority: a data frame of n X 4+7 containing gene priority (aggregated) information, where n is the number of genes, and the 4 columns are "name" (gene names), "rank" (ranks of the priority scores), "rating" (the 5-star score/rating), "description" (gene description), and 7 seed info columns including "seed" (whether or not seed genes), "nGene" (nearby genes), "cGene" (conformation genes), "eGene" (eQTL gens), "dGene" (disease genes), "pGene" (phenotype genes), and "fGene" (function genes)
- predictor: a data frame containing predictor matrix, with each column/predictor for either priority score/rating, or priorty rank or priority p-value
- metag: an "igraph" object
- list_pNode: a list of "pNode" objects

Note

none

df_score <- xPierMatrix(ls_pNode)
# get evidence for targets
eTarget <- xPierMatrix(ls_pNode, displayBy="evidence")
# get target priority in a discovery mode
dTarget <- xPierMatrix(ls_pNode, displayBy="pvalue",
aggregateBy="fishers")

## End(Not run)
```

---

xPierPathways *Function to prioritise pathways based on enrichment analysis of top prioritised genes*

Description

xPierPathways is supposed to prioritise pathways given prioritised genes and the ontology in query. It returns an object of class "eTerm". It is done via enrichment analysis.

Usage

```
xPierPathways(pNode, priority.top = 100, background = NULL,
ontology = NA, size.range = c(10, 2000), min.overlap = 3,
which.distance = NULL, test = c("hypergeo", "fisher", "binomial"),
background.annotatable.only = NULL, p.tail = c("one-tail",
"two-tails"), p.adjust.method = c("BH", "BY", "bonferroni", "holm",
"hochberg", "hommel"), ontology.algorithm = c("none", "pc", "elim",
"lea"), elim.pvalue = 0.01, lea.depth = 2,
path.mode = c("all_paths", "shortest_paths", "all_shortest_paths"),
true.path.rule = FALSE, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget")
priority.top	the number of the top targets used for enrichment analysis. By default, it sets to 100
background	a background vector. It contains a list of Gene Symbols as the test background. If NULL, by default all annotatable are used as background
ontology	the ontology supported currently. By default, it is 'NA' to disable this option. Pre-built ontology and annotation data are detailed in xDefineOntology.
size.range	the minimum and maximum size of members of each term in consideration. By default, it sets to a minimum of 10 but no more than 2000
min.overlap	the minimum number of overlaps. Only those terms with members that overlap with input data at least min.overlap (3 by default) will be processed
which.distance	which terms with the distance away from the ontology root (if any) is used to restrict terms in consideration. By default, it sets to 'NULL' to consider all distances
test	the statistic test used. It can be "fisher" for using fisher's exact test, "hypergeo" for using hypergeometric test, or "binomial" for using binomial test. Fisher's exact test is to test the independence between gene group (genes belonging to a group or not) and gene annotation (genes annotated by a term or not), and thus compare sampling to the left part of background (after sampling without replacement). Hypergeometric test is to sample at random (without replacement) from the background containing annotated and non-annotated genes, and thus compare sampling to background. Unlike hypergeometric test, binomial test is to sample at random (with replacement) from the background with the constant probability. In terms of the ease of finding the significance, they are in order: hypergeometric test > binomial test > fisher's exact test. In other words, in terms of the calculated p-value, hypergeometric test < binomial test < fisher's exact test
background.annotatable.only	logical to indicate whether the background is further restricted to the annotatable. By default, it is NULL: if ontology.algorithm is not 'none', it is always TRUE; otherwise, it depends on the background (if not provided, it will be TRUE; otherwise FALSE). Surely, it can be explicitly stated
p.tail	the tail used to calculate p-values. It can be either "two-tails" for the significance based on two-tails (ie both over- and under-overrepresentation) or "one-tail" (by default) for the significance based on one tail (ie only over-representation)
p.adjust.method	the method used to adjust p-values. It can be one of "BH", "BY", "bonferroni", "holm", "hochberg" and "hommel". The first two methods "BH" (widely used) and "BY" control the false discovery rate (FDR: the expected proportion of false discoveries amongst the rejected hypotheses); the last four methods "bonferroni", "holm", "hochberg" and "hommel" are designed to give strong control of the family-wise error rate (FWER). Notes: FDR is a less stringent condition than FWER
ontology.algorithm	the algorithm used to account for the hierarchy of the ontology. It can be one of "none", "pc", "elim" and "lea". For details, please see 'Note' below
elim.pvalue	the parameter only used when "ontology.algorithm" is "elim". It is used to control how to declare a signficantly enriched term (and subsequently all genes in this term are eliminated from all its ancestors)

lea.depth	the parameter only used when "ontology.algorithm" is "lea". It is used to control how many maximum depth is used to consider the children of a term (and subsequently all genes in these children term are eliminated from the use for the recalculation of the signifance at this term)
path.mode	the mode of paths induced by vertices/nodes with input annotation data. It can be "all_paths" for all possible paths to the root, "shortest_paths" for only one path to the root (for each node in query), "all_shortest_paths" for all shortest paths to the root (i.e. for each node, find all shortest paths with the equal lengths)
true.path.rule	logical to indicate whether the true-path rule should be applied to propagate annotations. By default, it sets to false
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to false for no display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details

Value

an object of class "eTerm", a list with following components:

- term_info: a matrix of nTerm X 4 containing snp/gene set information, where nTerm is the number of terms, and the 4 columns are "id" (i.e. "Term ID"), "name" (i.e. "Term Name"), "namespace" and "distance"
- annotation: a list of terms containing annotations, each term storing its annotations. Always, terms are identified by "id"
- data: a vector containing input data in consideration. It is not always the same as the input data as only those mappable are retained
- background: a vector containing the background data. It is not always the same as the input data as only those mappable are retained
- overlap: a list of overlapped snp/gene sets, each storing snps overlapped between a snp/gene set and the given input data (i.e. the snps of interest). Always, gene sets are identified by "id"
- zscore: a vector containing z-scores
- pvalue: a vector containing p-values
- adjp: a vector containing adjusted p-values. It is the p value but after being adjusted for multiple comparisons
- call: the call that produced this result

Note

The interpretation of the algorithms used to account for the hierarchy of the ontology is:

- "none": does not consider the ontology hierarchy at all.
- "lea": computers the significance of a term in terms of the significance of its children at the maximum depth (e.g. 2). Precisely, once snps are already annotated to any children terms with a more signficance than itself, then all these snps are eliminated from the use for the recalculation of the signifance at that term. The final p-values takes the maximum of the original p-value and the recalculated p-value.
- "elim": computers the significance of a term in terms of the significance of its all children. Precisely, once snps are already annotated to a signficantly enriched term under the cutoff of e.g. pvalue<1e-2, all these snps are eliminated from the ancestors of that term).

- "pc": requires the significance of a term not only using the whole snps as background but also using snps annotated to all its direct parents/ancestors as background. The final p-value takes the maximum of both p-values in these two calculations.
- "Notes": the order of the number of significant terms is: "none" > "lea" > "elim" > "pc".

xPierROCR *Function to assess the dTarget performance via ROC and Precision-Recall (PR) analysis*

Description

xPierROCR is supposed to assess the dTarget performance via Receiver Operating Characteristic (ROC) and Precision-Recall (PR) analysis. It requires three inputs: 1) Gold Standard Positive (GSP) targets; 2) Gold Standard Negative (GSN) targets; 3) dTarget containing predicted targets and predictive scores.

Usage

```
xPierROCR(dTarget, GSP, GSN, verbose = TRUE)
```

Arguments

dTarget	a data frame containing dTargets along with predictive scores. It has two columns: 1st column for target, 2nd column for predictive scores (the higher the better). Alternatively, it can be an object of class "pNode" (or "sTarget" or "dTarget") from which a data frame is extracted
GSP	a vector containing Gold Standard Positives (GSP)
GSN	a vector containing Gold Standard Negatives (GSN)
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to TRUE for display

Value

an object of the class "dTarget", a list with following components:

- priority: a data frame of nGene X 7 containing gene priority (aggregated) information, where nGene is the number of genes, and the 7 columns are "GS" (either 'GSP', or 'GSN', or 'NEW'), "name" (gene names), "rank" (ranks of the priority scores), "pvalue" (the aggregated p-value, converted from empirical cumulative distribution of the probability of being GSP), "fdr" (fdr adjusted from the aggregated p-value), "priority" (-log10(pvalue) but rescaled into the 5-star ratings), "description" (gene description) and seed info including "Overall" for the number of different types of seeds, followed by details on individual type of seeds (that is, "OMIM", "Phenotype", "Function", "nearbyGenes", "eQTL", "HiC")
- predictor: a data frame containing predictor matrix, with each column/predictor for either priority score, or priorty rank or priority p-value
- metag: an "igraph" object
- pPerf: a "pPerf" object, with components "PRS", "AUROC", "Fmax", "ROC_perf", "PR_perf", "Pred_obj"

Note

AUC: the area under ROC F-measure: the maximum of a harmonic mean between precision and recall along PR curve

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
```

```
## Not run:
dTarget <- xPierROCR(dTarget, GSP, GSN)
gp <- xPredictCompare(dTarget$pPerf)

## End(Not run)
```

`xPierSNPs` *Function to prioritise genes given a list of seed SNPs together with the significance level (e.g. GWAS reported p-values)*

Description

`xPierSNPs` is supposed to prioritise genes given a list of seed SNPs together with the significance level. To prioritise genes, it first defines and scores seed genes: nearby genes, eQTL genes and Hi-C genes. With seed genes and their scores, it then uses Random Walk with Restart (RWR) to calculate the affinity score of all nodes in the input graph to the seed genes. The priority score is the affinity score. Parallel computing is also supported for Linux-like or Windows operating systems. It returns an object of class "pNode".

Usage

```
xPierSNPs(data, include.LD = NA, LD.customised = NULL, LD.r2 = 0.8,
significance.threshold = 5e-05, score.cap = 10,
distance.max = 2000, decay.kernel = c("slow", "constant", "linear",
"rapid"), decay.exponent = 2, GR.SNP = c("dbSNP_GWAS",
"dbSNP_Common", "dbSNP_Single"), GR.Gene = c("UCSC_knownGene",
"UCSC_knownCanonical"), include.TAD = c("none", "GM12878", "IMR90",
"MSC", "TRO", "H1", "MES", "NPC"), include.eQTL = NA,
eQTL.customised = NULL, include.HiC = NA,
cdf.function = c("empirical", "exponential"),
relative.importance = c(1/3, 1/3, 1/3), scoring.scheme = c("max",

RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

`data`	a named input vector containing the sinificance level for nodes (dbSNP). For this named vector, the element names are dbSNP ID (or in the format such as

'chr16:28525386'), the element values for the significance level (measured as p-value or fdr). Alternatively, it can be a matrix or data frame with two columns: 1st column for dbSNP, 2nd column for the significance level

`include.LD` additional SNPs in LD with Lead SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, LD SNPs will be included based on one or more of 26 populations and 5 super populations from 1000 Genomics Project data (phase 3). The population can be one of 5 super populations ("AFR", "AMR", "EAS", "EUR", "SAS"), or one of 26 populations ("ACB", "ASW", "BEB", "CDX", "CEU", "CHB", "CHS", "CLM", "ESN", "FIN", "GBR", "GIH", "GWD", "IBS", "ITU", "JPT", "KHV", "LWK", "MSL", "MXL", "PEL", "PJL", "PUR", "STU", "TSI", "YRI"). Explanations for population code can be found at http://www.1000genomes.org/faq/which-populations-are-part-your-study

`LD.customised` a user-input matrix or data frame with 3 columns: 1st column for Lead SNPs, 2nd column for LD SNPs, and 3rd for LD r2 value. It is designed to allow the user analysing their pre-calculated LD info. This customisation (if provided) has the high priority over built-in LD SNPs

`LD.r2` the LD r2 value. By default, it is 0.8, meaning that SNPs in LD (r2>=0.8) with input SNPs will be considered as LD SNPs. It can be any value from 0.8 to 1

`significance.threshold` the given significance threshold. By default, it is set to NULL, meaning there is no constraint on the significance level when transforming the significance level of SNPs into scores. If given, those SNPs below this are considered significant and thus scored positively. Instead, those above this are considered insigificant and thus receive no score

`score.cap` the maximum score being capped. By default, it is set to 10. If NULL, no capping is applied

`distance.max` the maximum distance between genes and SNPs. Only those genes no far way from this distance will be considered as seed genes. This parameter will influence the distance-component weights calculated for nearby SNPs per gene

`decay.kernel` a character specifying a decay kernel function. It can be one of 'slow' for slow decay, 'linear' for linear decay, and 'rapid' for rapid decay. If no distance weight is used, please select 'constant'

`decay.exponent` an integer specifying a decay exponent. By default, it sets to 2

`GR.SNP` the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19). It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly

`GR.Gene` the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify

your file RData path in "RData.location". Note: you can also load your customised GR object directly

`include.TAD` TAD boundary regions are also included. By default, it is 'none' to disable this option. Otherwise, inclusion of a TAD dataset to pre-filter SNP-nGene pairs (i.e. only those within a TAD region will be kept). TAD datasets can be one of "GM12878" (lymphoblast), "IMR90" (fibroblast), "MSC" (mesenchymal stem cell) ,"TRO" (trophoblasts-like cell), "H1" (embryonic stem cell), "MES" (mesendoderm) and "NPC" (neural progenitor cell). Explanations can be found at http://dx.doi.org/10.1016/j.celrep.2016.10.061

`include.eQTL` the eQTL supported currently. By default, it is 'NA' to disable this option. Pre-built eQTL datasets are detailed in `xDefineEQTL`

`eQTL.customised`

a user-input matrix or data frame with 4 columns: 1st column for SNPs/eQTLs, 2nd column for Genes, 3rd for eQTL mapping significance level (p-values or FDR), and 4th for contexts (required even though only one context is input). Alternatively, it can be a file containing these 4 columns. It is designed to allow the user analysing their eQTL data. This customisation (if provided) will populate built-in eQTL data

`include.HiC` genes linked to input SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, those genes linked to SNPs will be included according to Promoter Capture HiC (PCHiC) datasets. Pre-built HiC datasets are detailed in `xDefineHIC`

`cdf.function` a character specifying a Cumulative Distribution Function (cdf). It can be one of 'exponential' based on exponential cdf, 'empirical' for empirical cdf

`relative.importance`

a vector specifying the relative importance of nearby genes, eQTL genes and HiC genes. By default, it sets c(1/3, 1/3, 1/3)

`scoring.scheme` the method used to calculate seed gene scores under a set of SNPs. It can be one of "sum" for adding up, "max" for the maximum, and "sequential" for the sequential weighting. The sequential weighting is done via: $\sum_{i=1} \frac{R_i}{i}$, where R_i is the i^{th} rank (in a descreasing order)

`network` the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with

the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix`
the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

multicores	an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details

Value

an object of class "pNode", a list with following components:

- priority: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 6 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object
- SNP: a data frame of nSNP X 4 containing input SNPs and/or LD SNPs info, where nSNP is the number of input SNPs and/or LD SNPs, and the 4 columns are "SNP" (dbSNP), "Score" (the SNP score), "Pval" (the SNP p-value), "Flag" (indicative of Lead SNPs or LD SNPs)
- Gene2SNP: a data frame of nPair X 3 containing Gene-SNP pair info, where nPair is the number of Gene-SNP pairs, and the 3 columns are "Gene" (seed genes), "SNP" (dbSNP), "Score" (an SNP's genetic influential score on a seed gene)
- nGenes: if not NULL, it is a data frame containing nGene-SNP pair info
- eGenes: if not NULL, it is a data frame containing eGene-SNP pair info per context
- cGenes: if not NULL, it is a data frame containing cGene-SNP pair info per context

Note

The prioritisation procedure (from SNPs to target genes) consists of following steps:

- i) xSNPscores used to calculate the SNP score.
- ii) xSNP2nGenes used to define and score the nearby genes.
- iii) xSNP2eGenes used to define and score the eQTL genes.
- iv) xSNP2cGenes used to define and score the HiC genes.
- v) define seed genes as the nearby genes in ii) and the eQTL genes in iii) and the HiC genes in iv), which are then scored in an integrative manner.
- vi) xPierGenes used to prioritise genes using an input graph and a list of seed genes and their scores from v). The priority score is the affinity score estimated by Random Walk with Restart (RWR), measured as the affinity of all nodes in the graph to the seeds.

`xPierSNPsAdv` *Function to prepare genetic predictors given a list of seed SNPs together with the significance level (e.g. GWAS reported p-values)*

Description

`xPierSNPsAdv` is supposed to prepare genetic predictors given a list of seed SNPs together with the significance level (e.g. GWAS reported p-values). Internally it calls `xPierSNPs` to prepare the distance predictor, the eQTL predictors (if required) and the HiC predictors (if required). It returns a list of class "pNode" objects.

Usage

```
xPierSNPsAdv(data, include.LD = NA, LD.customised = NULL,
LD.r2 = 0.8, significance.threshold = 5e-05, score.cap = 10,
distance.max = 2000, decay.kernel = c("slow", "constant", "linear",
"rapid"), decay.exponent = 2, GR.SNP = c("dbSNP_GWAS",
"dbSNP_Common", "dbSNP_Single"), GR.Gene = c("UCSC_knownGene",
"UCSC_knownCanonical"), include.TAD = c("none", "GM12878", "IMR90",
```

```
"MSC", "TRO", "H1", "MES", "NPC"), include.eQTL = NA,
eQTL.customised = NULL, include.HiC = NA,
cdf.function = c("empirical", "exponential"),
scoring.scheme = c("max", "sum", "sequential"),
network = c("STRING_highest", "STRING_high", "STRING_medium",
"STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high",
"PCommonsDN_medium", "PCommonsDN_Reactome", "PCommonsDN_KEGG",
"PCommonsDN_HumanCyc", "PCommonsDN_PID", "PCommonsDN_PANTHER",
"PCommonsDN_ReconX", "PCommonsDN_TRANSFAC", "PCommonsDN_PhosphoSite",
"PCommonsDN_CTD", "KEGG", "KEGG_metabolism", "KEGG_genetic",
"KEGG_environmental", "KEGG_cellular", "KEGG_organismal",
"KEGG_disease",
"REACTOME"), STRING.only = c(NA, "neighborhood_score", "fusion_score",
"cooccurence_score", "coexpression_score", "experimental_score",
"database_score", "textmining_score")[1], weighted = FALSE,
network.customised = NULL, seeds.inclusive = TRUE,
normalise = c("laplacian", "row", "column", "none"), restart = 0.7,
normalise.affinity.matrix = c("none", "quantile"), parallel = TRUE,
multicores = NULL, verbose = TRUE, verbose.details = FALSE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a named input vector containing the sinificance level for nodes (dbSNP). For this named vector, the element names are dbSNP ID (or in the format such as 'chr16:28525386'), the element values for the significance level (measured as p-value or fdr). Alternatively, it can be a matrix or data frame with two columns: 1st column for dbSNP, 2nd column for the significance level
include.LD	additional SNPs in LD with Lead SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, LD SNPs will be included based on one or more of 5 super-populations from 1000 Genomics Project data (phase 3). They are "AFR", "AMR", "EAS", "EUR", and "SAS". Explanations for population code can be found at http://www.1000genomes.org/faq/which-populations-are-part-your-s
LD.customised	a user-input matrix or data frame with 3 columns: 1st column for Lead SNPs, 2nd column for LD SNPs, and 3rd for LD r2 value. It is designed to allow the user analysing their pre-calculated LD info. This customisation (if provided) has the high priority over built-in LD SNPs
LD.r2	the LD r2 value. By default, it is 0.8, meaning that SNPs in LD (r2>=0.8) with input SNPs will be considered as LD SNPs. It can be any value from 0.8 to 1
significance.threshold	the given significance threshold. By default, it is set to NULL, meaning there is no constraint on the significance level when transforming the significance level of SNPs into scores. If given, those SNPs below this are considered significant and thus scored positively. Instead, those above this are considered insigificant and thus receive no score
score.cap	the maximum score being capped. By default, it is set to 10. If NULL, no capping is applied
distance.max	the maximum distance between genes and SNPs. Only those genes no far way from this distance will be considered as seed genes. This parameter will influence the distance-component weights calculated for nearby SNPs per gene

`decay.kernel` a character specifying a decay kernel function. It can be one of 'slow' for slow decay, 'linear' for linear decay, and 'rapid' for rapid decay. If no distance weight is used, please select 'constant'

`decay.exponent` an integer specifying a decay exponent. By default, it sets to 2

`GR.SNP` the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19). It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly

`GR.Gene` the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly

`include.TAD` TAD boundary regions are also included. By default, it is 'none' to disable this option. Otherwise, inclusion of a TAD dataset to pre-filter SNP-nGene pairs (i.e. only those within a TAD region will be kept). TAD datasets can be one of "GM12878" (lymphoblast), "IMR90" (fibroblast), "MSC" (mesenchymal stem cell) ,"TRO" (trophoblasts-like cell), "H1" (embryonic stem cell), "MES" (mesendoderm) and "NPC" (neural progenitor cell). Explanations can be found at http://dx.doi.org/10.1016/j.celrep.2016.10.061

`include.eQTL` the eQTL supported currently. By default, it is 'NA' to disable this option. Pre-built eQTL datasets are detailed in `xDefineEQTL`

`eQTL.customised`
a user-input matrix or data frame with 4 columns: 1st column for SNPs/eQTLs, 2nd column for Genes, 3rd for eQTL mapping significance level (p-values or FDR), and 4th for contexts (required even though only one context is input). Alternatively, it can be a file containing these 4 columns. It is designed to allow the user analysing their eQTL data. This customisation (if provided) will populate built-in eQTL data

`include.HiC` genes linked to input SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, those genes linked to SNPs will be included according to Promoter Capture HiC (PCHiC) datasets. Pre-built HiC datasets are detailed in `xDefineHIC`

`cdf.function` a character specifying a Cumulative Distribution Function (cdf). It can be one of 'exponential' based on exponential cdf, 'empirical' for empirical cdf

`scoring.scheme` the method used to calculate seed gene scores under a set of SNPs. It can be one of "sum" for adding up, "max" for the maximum, and "sequential" for the sequential weighting. The sequential weighting is done via: $\sum_{i=1} \frac{R_i}{i}$, where R_i is the i^{th} rank (in a descreasing order)

`network` the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex
Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix` the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores` an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose` logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`verbose.details` logical to indicate whether the detailed messages from being-called functions will be displayed in the screen. By default, it sets to FALSE enabling messages

`RData.location` the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

A list of class "pNode" objects, each object having a list with following components:

- `priority`: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 6 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object
- `SNP`: a data frame of nSNP X 4 containing input SNPs and/or LD SNPs info, where nSNP is the number of input SNPs and/or LD SNPs, and the 4 columns are "SNP" (dbSNP), "Score" (the SNP score), "Pval" (the SNP p-value), "Flag" (indicative of Lead SNPs or LD SNPs)
- `Gene2SNP`: a data frame of nPair X 3 containing Gene-SNP pair info, where nPair is the number of Gene-SNP pairs, and the 3 columns are "Gene" (seed genes), "SNP" (dbSNP), "Score" (an SNP's genetic influential score on a seed gene)
- `nGenes`: if not NULL, it is a data frame containing nGene-SNP pair info
- `eGenes`: if not NULL, it is a data frame containing eGene-SNP pair info per context
- `cGenes`: if not NULL, it is a data frame containing cGene-SNP pair info per context

Note

This function calls xPierSNPs in a loop way generating the distance predictor, the eQTL predictors (if required) and the HiC predictors (if required).

xPierSNPsAdvABF *Function to prepare genetic predictors given GWAS summary data with eGenes identified through ABF*

Description

xPierSNPsAdvABF is supposed to prepare genetic predictors given GWAS summary data with eGenes identified through ABF. Internally it calls xPierSNPs to prepare the distance predictor and the HiC predictors (if required), and xPierABF to prepare the eQTL predictors (if required). It returns a list of class "pNode" objects.

Usage

```
xPierSNPsAdvABF(data, include.LD = NA, LD.customised = NULL,
LD.r2 = 0.8, significance.threshold = 5e-05, score.cap = 10,
distance.max = 2000, decay.kernel = c("slow", "constant", "linear",
"rapid"), decay.exponent = 2, GR.SNP = c("dbSNP_GWAS",
"dbSNP_Common", "dbSNP_Single"), GR.Gene = c("UCSC_knownGene",
"UCSC_knownCanonical"), include.TAD = c("none", "GM12878", "IMR90",
"MSC", "TRO", "H1", "MES", "NPC"), include.eQTL = c("CD14", "LPS2",
"LPS24", "IFN", "Bcell", "NK", "Neutrophil", "CD4", "CD8", "Blood",
```

```
"Monocyte", "shared_CD14", "shared_LPS2", "shared_LPS24",
"shared_IFN"),
include.HiC = NA, cdf.function = c("empirical", "exponential"),
scoring.scheme = c("max", "sum", "sequential"),
network = c("STRING_highest", "STRING_high", "STRING_medium",
"STRING_low", "PCommonsUN_high", "PCommonsUN_medium",
"PCommonsDN_high",
"PCommonsDN_medium", "PCommonsDN_Reactome", "PCommonsDN_KEGG",
"PCommonsDN_HumanCyc", "PCommonsDN_PID", "PCommonsDN_PANTHER",
"PCommonsDN_ReconX", "PCommonsDN_TRANSFAC", "PCommonsDN_PhosphoSite",
"PCommonsDN_CTD", "KEGG", "KEGG_metabolism", "KEGG_genetic",
"KEGG_environmental", "KEGG_cellular", "KEGG_organismal",
"KEGG_disease",
"REACTOME"), STRING.only = c(NA, "neighborhood_score", "fusion_score",
"cooccurence_score", "coexpression_score", "experimental_score",
"database_score", "textmining_score")[1], weighted = FALSE,
network.customised = NULL, seeds.inclusive = TRUE,
normalise = c("laplacian", "row", "column", "none"), restart = 0.7,
normalise.affinity.matrix = c("none", "quantile"), parallel = TRUE,
multicores = NULL, verbose = TRUE, verbose.details = FALSE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

data	a data frame storing GWAS summary data with following required columns 'snp', 'p' (p-value), 'effect' (the effect allele assessed), 'other' (other allele), 'b' (effect size for the allele assessed; log(odds ratio) for a case-control study), 'se' (standard error), 'suggestive' (logical, and those false only to define nGene/cGene; all used to define eGene)
include.LD	additional SNPs in LD with Lead SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, LD SNPs will be included based on one or more of 5 super-populations from 1000 Genomics Project data (phase 3). They are "AFR", "AMR", "EAS", "EUR", and "SAS". Explanations for population code can be found at http://www.1000genomes.org/faq/which-populations-are-part-your-s
LD.customised	a user-input matrix or data frame with 3 columns: 1st column for Lead SNPs, 2nd column for LD SNPs, and 3rd for LD r2 value. It is designed to allow the user analysing their pre-calculated LD info. This customisation (if provided) has the high priority over built-in LD SNPs
LD.r2	the LD r2 value. By default, it is 0.8, meaning that SNPs in LD (r2>=0.8) with input SNPs will be considered as LD SNPs. It can be any value from 0.8 to 1
significance.threshold	the given significance threshold. By default, it is set to NULL, meaning there is no constraint on the significance level when transforming the significance level of SNPs into scores. If given, those SNPs below this are considered significant and thus scored positively. Instead, those above this are considered insigificant and thus receive no score
score.cap	the maximum score being capped. By default, it is set to 10. If NULL, no capping is applied
distance.max	the maximum distance between genes and SNPs. Only those genes no far way from this distance will be considered as seed genes. This parameter will influence the distance-component weights calculated for nearby SNPs per gene

`decay.kernel` a character specifying a decay kernel function. It can be one of 'slow' for slow decay, 'linear' for linear decay, and 'rapid' for rapid decay. If no distance weight is used, please select 'constant'

`decay.exponent` an integer specifying a decay exponent. By default, it sets to 2

`GR.SNP` the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19). It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly

`GR.Gene` the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly

`include.TAD` TAD boundary regions are also included. By default, it is 'none' to disable this option. Otherwise, inclusion of a TAD dataset to pre-filter SNP-nGene pairs (i.e. only those within a TAD region will be kept). TAD datasets can be one of "GM12878" (lymphoblast), "IMR90" (fibroblast), "MSC" (mesenchymal stem cell) ,"TRO" (trophoblasts-like cell), "H1" (embryonic stem cell), "MES" (mesendoderm) and "NPC" (neural progenitor cell). Explanations can be found at http://dx.doi.org/10.1016/j.celrep.2016.10.061

`include.eQTL` the context-specific eQTL summary data supported currently. Contexts include "Bcell", "Blood", "CD14", "CD4", "CD8", "IFN", "LPS24", "LPS2", "Monocyte", "Neutrophil", "NK", "shared_CD14", "shared_IFN", "shared_LPS24", "shared_LPS2"

`include.HiC` genes linked to input SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, those genes linked to SNPs will be included according to Promoter Capture HiC (PCHiC) datasets. Pre-built HiC datasets are detailed in `xDefineHIC`

`cdf.function` a character specifying a Cumulative Distribution Function (cdf). It can be one of 'exponential' based on exponential cdf, 'empirical' for empirical cdf

`scoring.scheme` the method used to calculate seed gene scores under a set of SNPs. It can be one of "sum" for adding up, "max" for the maximum, and "sequential" for the sequential weighting. The sequential weighting is done via: $\sum_{i=1} \frac{R_i}{i}$, where R_i is the i^{th} rank (in a descreasing order)

`network` the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control

the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex
Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`seeds.inclusive`
logical to indicate whether non-network seed genes are included for prioritisation. If TRUE (by default), these genes will be added to the netowrk

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting

nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix`
: the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel`
: logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores`
: an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose`
: logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`verbose.details`
: logical to indicate whether the detailed messages from being-called functions will be displayed in the screen. By default, it sets to FALSE enabling messages

`RData.location`
: the characters to tell the location of built-in RData files. See `xRDataLoader` for details

`...`
: additional parameters used in xPierABF ("prior.eqtl", "prior.gwas", "prior.both", "cutoff.H4", "cutoff.pgwas")

Value

A list of class "pNode" objects, each object having a list with following components:

- `priority`: a matrix of nNode X 6 containing node priority information, where nNode is the number of nodes in the input graph, and the 6 columns are "name" (node names), "node" (1 for network genes, 0 for non-network seed genes), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight values), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), "description" (node description)
- g: an input "igraph" object
- `SNP`: a data frame of nSNP X 4 containing input SNPs and/or LD SNPs info, where nSNP is the number of input SNPs and/or LD SNPs, and the 4 columns are "SNP" (dbSNP), "Score" (the SNP score), "Pval" (the SNP p-value), "Flag" (indicative of Lead SNPs or LD SNPs)
- `Gene2SNP`: a data frame of nPair X 3 containing Gene-SNP pair info, where nPair is the number of Gene-SNP pairs, and the 3 columns are "Gene" (seed genes), "SNP" (dbSNP), "Score" (an SNP's genetic influential score on a seed gene)
- `nGenes`: if not NULL, it is a data frame containing nGene-SNP pair info
- `eGenes`: if not NULL, it is a data frame containing eGene-SNP pair info per context
- `cGenes`: if not NULL, it is a data frame containing cGene-SNP pair info per context

Note

This function calls `xPierSNPs` in a loop way generating the distance predictor, the eQTL predictors (if required) and the HiC predictors (if required).

xPierSNPsConsensus *Function to resolve relative importance of distance weight and eQTL weight priorising consensus gene ranks given a list of seed SNPs together with the significance level (e.g. GWAS reported p-values)*

Description

xPierSNPsConsensus is supposed to priorise genes given a list of seed SNPs together with the significance level. It is a parameter-free version of xPierSNPs identifying the consensus rank (less sensitive to the relative importance of the distance weight and eQTL weight). It returns an object of class "pNode" but appended with components on optimal distance weight and consensus info

Usage

```
xPierSNPsConsensus(data, include.LD = NA, LD.customised = NULL,
LD.r2 = 0.8, significance.threshold = 5e-05, distance.max = 2e+05,
decay.kernel = c("rapid", "slow", "linear"), decay.exponent = 2,

multicores = NULL, verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

data	a named input vector containing the sinificance level for nodes (dbSNP). For this named vector, the element names are dbSNP ID (or in the format such as 'chr16:28525386'), the element values for the significance level (measured as p-value or fdr). Alternatively, it can be a matrix or data frame with two columns: 1st column for dbSNP, 2nd column for the significance level
include.LD	additional SNPs in LD with Lead SNPs are also included. By default, it is 'NA' to disable this option. Otherwise, LD SNPs will be included based on one or more of 26 populations and 5 super populations from 1000 Genomics Project data (phase 3). The population can be one of 5 super populations ("AFR", "AMR", "EAS", "EUR", "SAS"), or one of 26 populations ("ACB", "ASW", "BEB", "CDX", "CEU", "CHB", "CHS", "CLM", "ESN", "FIN", "GBR", "GIH", "GWD", "IBS", "ITU", "JPT", "KHV", "LWK", "MSL", "MXL", "PEL", "PJL", "PUR", "STU", "TSI", "YRI"). Explanations for population code can be found at http://www.1000genomes.org/faq/which-populations-are-part-your-study
LD.customised	a user-input matrix or data frame with 3 columns: 1st column for Lead SNPs, 2nd column for LD SNPs, and 3rd for LD r2 value. It is designed to allow the user analysing their pre-calculated LD info. This customisation (if provided) has the high priority over built-in LD SNPs
LD.r2	the LD r2 value. By default, it is 0.8, meaning that SNPs in LD (r2>=0.8) with input SNPs will be considered as LD SNPs. It can be any value from 0.8 to 1
significance.threshold	the given significance threshold. By default, it is set to NULL, meaning there is no constraint on the significance level when transforming the significance level of SNPs into scores. If given, those SNPs below this are considered significant and thus scored positively. Instead, those above this are considered insigificant and thus receive no score
distance.max	the maximum distance between genes and SNPs. Only those genes no far way from this distance will be considered as seed genes. This parameter will influence the distance-component weights calculated for nearby SNPs per gene
decay.kernel	a character specifying a decay kernel function. It can be one of 'slow' for slow decay, 'linear' for linear decay, and 'rapid' for rapid decay
decay.exponent	an integer specifying a decay exponent. By default, it sets to 2
GR.SNP	the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19).

It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location"

`GR.Gene` the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location"

`include.eQTL` genes modulated by eQTL (also Lead SNPs or in LD with Lead SNPs) are also included. By default, it is 'NA' to disable this option. Otherwise, those genes modulated by eQTL will be included: immune stimulation in monocytes ('JKscience_TS1A' and 'JKscience_TS2B' for cis-eQTLs or 'JKscience_TS3A' for trans-eQTLs) from Science 2014, 343(6175):1246949; cis- and trans-eQTLs in B cells ('JKng_bcell') and in monocytes ('JKng_mono') from Nature Genetics 2012, 44(5):502-510; cis- and trans-eQTLs in neutrophils ('JKnc_neutro') from Nature Communications 2015, 7(6):7545; cis-eQTLs in NK cells ('JK_nk') which is unpublished. Also supported are GTEx cis-eQTLs from Science 2015, 348(6235):648-60, including 13 tissues: 'GTEx_Adipose_Subcutaneous','GTEx_Artery_Aorta','GT

`eQTL.customised`

a user-input matrix or data frame with 3 columns: 1st column for SNPs/eQTLs, 2nd column for Genes, and 3rd for eQTL mapping significance level (p-values or FDR). It is designed to allow the user analysing their eQTL data. This customisation (if provided) has the high priority over built-in eQTL data.

`cdf.function` a character specifying a Cumulative Distribution Function (cdf). It can be one of 'exponential' based on exponential cdf, 'empirical' for empirical cdf

`scoring.scheme` the method used to calculate seed gene scores under a set of SNPs. It can be one of "sum" for adding up, "max" for the maximum, and "sequential" for the sequential weighting. The sequential weighting is done via: $\sum_{i=1} \frac{R_i}{i}$, where R_i is the i^{th} rank (in a descreasing order)

`network` the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathways Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references).

For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addtion to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD

`weighted` logical to indicate whether edge weights should be considered. By default, it sets to false. If true, it only works for the network from the STRING database

`network.customised` an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network. If the user provides the "igraph" object with the "weight" edge attribute, RWR will assume to walk on the weighted network

`normalise` the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'

`restart` the restart probability used for Random Walk with Restart (RWR). The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)

`normalise.affinity.matrix` the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

`parallel` logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. Partly because parallel backends available will be system-specific (now only Linux or Mac OS). Also, it will depend on whether these two packages "foreach" and "doMC" have been installed

`multicores` an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled

`verbose` logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`RData.location` the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

an object of class "pNode", a list with following components:

- priority: a matrix of nNode X 4 containing node priority information, where nNode is the number of nodes in the input graph, and the 4 columns are "name" (node names), "seed" (1 for seeds, 0 for non-seeds), "weight" (weight/score values for seed genes), "priority" (the priority scores that are rescaled to the range [0,1]), "rank" (ranks of the priority scores), and two additional columns: 'driver' telling who drives the prioritisation ('nGenes','eGenes' or'both'), and 'consensus_rank'
- g: an input "igraph" object
- SNP: a data frame of nSNP X 3 containing input SNPs and/or LD SNPs info, where nSNP is the number of input SNPs and/or LD SNPs, and the 3 columns are "SNP" (dbSNP), "Score" (the SNP score), "Pval" (the SNP p-value)
- Gene2SNP: a matrix of Genes X SNPs, each non-zero cell telling an SNP's genetic influential score on a seed gene
- nGenes: the relative weight for nearby genes
- consensus: a matrix containing details on rank results by decreasing the relative importance of nGenes. In addition to rank matrix, it has columns 'rank_median' for median rank excluding two extremes 'n_1' (nGenes only) and 'n_0' (eGenes only), 'rank_MAD' for median absolute deviation, 'driver' telling who drives the prioritisation ('nGenes','eGenes' or'both'), 'consensus_rank' for the rank of the median rank list
- call: the call that produced this result

xPierSubnet *Function to identify a gene network from top prioritised genes*

Description

xPierSubnet is supposed to identify maximum-scoring gene subnetwork from a graph with the node information on priority scores, both are part of an object of class "pNode". It returns an object of class "igraph".

Usage

```
xPierSubnet(pNode, priority.quantile = 0.1, network = c(NA,
"STRING_highest", "STRING_high", "STRING_medium", "STRING_low",
"PCommonsUN_high", "PCommonsUN_medium", "PCommonsDN_high",
"PCommonsDN_medium", "PCommonsDN_Reactome", "PCommonsDN_KEGG",
"PCommonsDN_HumanCyc", "PCommonsDN_PID", "PCommonsDN_PANTHER",
"PCommonsDN_ReconX", "PCommonsDN_TRANSFAC", "PCommonsDN_PhosphoSite",
"PCommonsDN_CTD", "KEGG", "KEGG_metabolism", "KEGG_genetic",
"KEGG_environmental", "KEGG_cellular", "KEGG_organismal",
"KEGG_disease",
"REACTOME"), STRING.only = c(NA, "neighborhood_score", "fusion_score",
"cooccurence_score", "coexpression_score", "experimental_score",
"database_score", "textmining_score")[1], network.customised = NULL,
subnet.significance = 0.01, subnet.size = NULL,
test.permutation = FALSE, num.permutation = 100,
respect = c("none", "degree"), aggregateBy = c("Ztransform",
"fishers", "logistic", "orderStatistic"), verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata")
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget")
priority.quantile	the quantile of the top priority genes. By default, 10 analysis. If NULL or NA, all prioritised genes will be used
network	the built-in network. Currently two sources of network information are supported: the STRING database (version 10) and the Pathway Commons database (version 7). STRING is a meta-integration of undirect interactions from the functional aspect, while Pathways Commons mainly contains both undirect and direct interactions from the physical/pathway aspect. Both have scores to control

the confidence of interactions. Therefore, the user can choose the different quality of the interactions. In STRING, "STRING_highest" indicates interactions with highest confidence (confidence scores>=900), "STRING_high" for interactions with high confidence (confidence scores>=700), "STRING_medium" for interactions with medium confidence (confidence scores>=400), and "STRING_low" for interactions with low confidence (confidence scores>=150). For undirect/physical interactions from Pathways Commons, "PCommonsUN_high" indicates undirect interactions with high confidence (supported with the PubMed references plus at least 2 different sources), "PCommonsUN_medium" for undirect interactions with medium confidence (supported with the PubMed references). For direct (pathway-merged) interactions from Pathways Commons, "PCommonsDN_high" indicates direct interactions with high confidence (supported with the PubMed references plus at least 2 different sources), and "PCommonsUN_medium" for direct interactions with medium confidence (supported with the PubMed references). In addition to pooled version of pathways from all data sources, the user can also choose the pathway-merged network from individual sources, that is, "PCommonsDN_Reactome" for those from Reactome, "PCommonsDN_KEGG" for those from KEGG, "PCommonsDN_HumanCyc" for those from HumanCyc, "PCommonsDN_PID" for those froom PID, "PCommonsDN_PANTHER" for those from PANTHER, "PCommonsDN_ReconX" for those from ReconX, "PCommonsDN_TRANSFAC" for those from TRANSFAC, "PCommonsDN_PhosphoSite" for those from PhosphoSite, and "PCommonsDN_CTD" for those from CTD. For direct (pathway-merged) interactions sourced from KEGG, it can be 'KEGG' for all, 'KEGG_metabolism' for pathways grouped into 'Metabolism', 'KEGG_genetic' for 'Genetic Information Processing' pathways, 'KEGG_environmental' for 'Environmental Information Processing' pathways, 'KEGG_cellular' for 'Cellular Processes' pathways, 'KEGG_organismal' for 'Organismal Systems' pathways, and 'KEGG_disease' for 'Human Diseases' pathways. 'REACTOME' for protein-protein interactions derived from Reactome pathways

`STRING.only` the further restriction of STRING by interaction type. If NA, no such restriction. Otherwide, it can be one or more of "neighborhood_score","fusion_score","cooccurence_score","coex
Useful options are c("experimental_score","database_score"): only experimental data (extracted from BIND, DIP, GRID, HPRD, IntAct, MINT, and PID) and curated data (extracted from Biocarta, BioCyc, GO, KEGG, and Reactome) are used

`network.customised`
an object of class "igraph". By default, it is NULL. It is designed to allow the user analysing their customised network data that are not listed in the above argument 'network'. This customisation (if provided) has the high priority over built-in network

`subnet.significance`
the given significance threshold. By default, it is set to NULL, meaning there is no constraint on nodes/genes. If given, those nodes/genes with p-values below this are considered significant and thus scored positively. Instead, those p-values above this given significance threshold are considered insigificant and thus scored negatively

`subnet.size` the desired number of nodes constrained to the resulting subnet. It is not nulll, a wide range of significance thresholds will be scanned to find the optimal significance threshold leading to the desired number of nodes in the resulting subnet. Notably, the given significance threshold will be overwritten by this option

`test.permutation`
: logical to indicate whether the permutation test is perform to estimate the significance of identified network with the same number of nodes. By default, it sets to false

`num.permutation`
: the number of permutations generating the null distribution of the identified network

`respect`
: how to respect nodes to be sampled. It can be one of 'none' (randomly sampling) and 'degree' (degree-preserving sampling)

`aggregateBy`
: the aggregate method used to aggregate edge confidence p-values. It can be either "orderStatistic" for the method based on the order statistics of p-values, or "fishers" for Fisher's method, "Ztransform" for Z-transform method, "logistic" for the logistic method. Without loss of generality, the Z-transform method does well in problems where evidence against the combined null is spread widely (equal footings) or when the total evidence is weak; Fisher's method does best in problems where the evidence is concentrated in a relatively small fraction of the individual tests or when the evidence is at least moderately strong; the logistic method provides a compromise between these two. Notably, the aggregate methods 'Ztransform' and 'logistic' are preferred here

`verbose`
: logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

`RData.location`
: the characters to tell the location of built-in RData files. See `xRDataLoader` for details

Value

a subgraph with a maximum score, an object of class "igraph". It has ndoe attributes: signficance, score, type, priority (part of the "pNode" object). If permutation test is enabled, it also has a graph attribute (combinedP) and an edge attribute (edgeConfidence)

Note

The priority score will be first scaled to the range x=[0 100] and then is converted to pvalue-like significant level: 10^(-x). Next, `xSubneterGenes` is used to identify a maximum-scoring gene subnetwork that contains as many highly prioritised genes as possible but a few lowly prioritised genes as linkers. An iterative procedure of scanning different priority thresholds is also used to identify the network with a desired number of nodes/genes. Notably, the preferential use of the same network as used in gene-level prioritisation is due to the fact that gene-level affinity/priority scores are smoothly distributed over the network after being walked. In other words, the chance of identifying such a gene network enriched with top prioritised genes is much higher.

`xPierTrack` *Function to visualise a prioritised gene using track plot*

Description

`xPierTrack` is supposed to visualise a prioritised gene using track plot. Priority for the gene in query is displayed on the data track and nearby genes on the annotation track. Genomic locations on the X-axis are indicated on the X-axis, and the gene in query is highlighted. If SNPs are also provided, SNP annotation track will be also displayed at the bottom.

Usage

```
xPierTrack(pNode, priority.top = NULL, target.query = NULL,
window = 1e+06, nearby = NULL, query.highlight = TRUE,
track.ideogram = TRUE, track.genomeaxis = TRUE,
name.datatrack = "5-star rating\n(Priority index)",
name.annotrack = "Targets", GR.Gene = c("UCSC_knownGene",
"UCSC_knownCanonical"), SNPs = NULL, max.num.SNPs = 50,
GR.SNP = c("dbSNP_GWAS", "dbSNP_Common", "dbSNP_Single"),
verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget")
priority.top	the number of the top targets used for track plot. By default, it is NULL meaning all targets are used
target.query	which gene in query will be visualised. If NULL, the target gene with the top priority will be displayed
window	the maximum distance defining nearby genes around the target gene in query. By default it is 1e6
nearby	the maximum number defining nearby genes around the target gene in query. By default it is NULL. If not NULL, it will overwrite the parameter 'window'
query.highlight	logical to indicate whether the gene in query will be highlighted
track.ideogram	logical to indicate whether ideogram track is shown. By default, it is TRUE
track.genomeaxis	logical to indicate whether genome axis track is shown. By default, it is TRUE
name.datatrack	the name for the data track. By default, it is "Priority index"
name.annotrack	the name for the annotation track. By default, it is "Genes". If NULL, the title for annotation track will be hided
GR.Gene	the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location"
SNPs	a input vector containing SNPs. SNPs should be provided as dbSNP ID (ie starting with rs). Alternatively, they can be in the format of 'chrN:xxx', where N is either 1-22 or X, xxx is genomic positional number; for example, 'chr16:28525386'. By default, it is NULL meaning the SNP annotation track will be not displayed
max.num.SNPs	the maximum number (50 by default) of SNPs to be shown. If NULL, no such restriction. Also this parameter only works when the SNP annotation track is enabled
GR.SNP	the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19).

	It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly
`verbose`	logical to indicate whether the messages will be displayed in the screen. By default, it sets to false for no display
`RData.location`	the characters to tell the location of built-in RData files. See `xRDataLoader` for details
`...`	additional graphic parameters. For example, the parameter "add" allows the plot added to an existing plotting canvas without re-initialising. See `http://www.rdocumentation.org/packages/Gviz/topics/plotTracks` for the complete list.

Value

a list of GenomeGraph tracks, each one augmented by the computed image map coordinates in the 'imageMap' slot, along with the additional 'ImageMap' object 'titles' containing information about the title panels.

Note

none

xPierTrackAdv *Function to visualise a list of prioritised genes using advanced track plot*

Description

xPierTrackAdv is supposed to visualise prioritised genes using advanced track plot. Internally, it calls the function 'xPierTrack' per gene.

Usage

```
xPierTrackAdv(pNode, priority.top = NULL, targets.query = NULL,
window = 1e+06, nearby = NULL, query.highlight = TRUE,
track.ideogram = TRUE, track.genomeaxis = TRUE,
name.datatrack = "Priority index", name.annotrack = "Genes",
GR.Gene = c("UCSC_knownGene", "UCSC_knownCanonical"), SNPs = NULL,
GR.SNP = c("dbSNP_GWAS", "dbSNP_Common", "dbSNP_Single"),
verbose = TRUE,
RData.location = "http://galahad.well.ox.ac.uk/bigdata", ...)
```

Arguments

pNode	an object of class "pNode" (or "sTarget" or "dTarget")
priority.top	the number of the top targets used for track plot. By default, it is NULL meaning all targets are used
targets.query	which genes in query will be visualised. If NULL, the target gene with the top priority will be displayed
window	the maximum distance defining nearby genes around the target gene in query. By default it is 1e6
nearby	the maximum number defining nearby genes around the target gene in query. By default it is NULL. If not NULL, it will overwrite the parameter 'window'
query.highlight	logical to indicate whether the gene in query will be highlighted
track.ideogram	logical to indicate whether ideogram track is shown. By default, it is TRUE
track.genomeaxis	logical to indicate whether genome axis track is shown. By default, it is TRUE
name.datatrack	the name for the data track. By default, it is "Priority index"
name.annotrack	the name for the annotation track. By default, it is "Target genes"

GR.Gene	the genomic regions of genes. By default, it is 'UCSC_knownGene', that is, UCSC known genes (together with genomic locations) based on human genome assembly hg19. It can be 'UCSC_knownCanonical', that is, UCSC known canonical genes (together with genomic locations) based on human genome assembly hg19. Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to Gene Symbols. Then, tell "GR.Gene" with your RData file name (with or without extension), plus specify your file RData path in "RData.location"
SNPs	a input vector containing SNPs. SNPs should be provided as dbSNP ID (ie starting with rs). Alternatively, they can be in the format of 'chrN:xxx', where N is either 1-22 or X, xxx is genomic positional number; for example, 'chr16:28525386'. By default, it is NLL meaning the SNP annotation track will be not displayed
GR.SNP	the genomic regions of SNPs. By default, it is 'dbSNP_GWAS', that is, SNPs from dbSNP (version 146) restricted to GWAS SNPs and their LD SNPs (hg19). It can be 'dbSNP_Common', that is, Common SNPs from dbSNP (version 146) plus GWAS SNPs and their LD SNPs (hg19). Alternatively, the user can specify the customised input. To do so, first save your RData file (containing an GR object) into your local computer, and make sure the GR object content names refer to dbSNP IDs. Then, tell "GR.SNP" with your RData file name (with or without extension), plus specify your file RData path in "RData.location". Note: you can also load your customised GR object directly
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to false for no display
RData.location	the characters to tell the location of built-in RData files. See xRDataLoader for details
...	additional graphic parameters. For example, the parameter "strip" allows the panel title is hided (FALSE), shown (TRUE) or without the background (lattice::strip.custom(bg="transparent")); the parameter "layout" allows specification of the layout (the first element for the columns and the second element for the rows). See http://www.rdocumentation.org/packages/lattice/topics/xyplot for the complete list.

Value

an object of class "trellis"

Note

none

`xPredictCompare` *Function to compare prediction performance results*

Description

`xPredictCompare` is supposed to compare prediction performance results. It returns an object of class "ggplot".

Usage

```
xPredictCompare(list_pPerf, displayBy = c("ROC", "PR"),
type = c("curve", "bar"), sort = TRUE, detail = TRUE,
facet = FALSE, font.family = "sans", signature = TRUE)
```

Arguments

`list_pPerf`	a list of "pPerf" objects
`displayBy`	which performance will be used for comparison. It can be "ROC" for ROC curve (by default), "PR" for PR curve
`type`	the type of plot to draw. It can be "curve" for curve plot (by default), "bar" for bar plot
`sort`	logical to indicate whether to sort methods according to performance. By default, it sets TRUE
`detail`	logical to indicate whether to label methods along with performance. By default, it sets TRUE

facet	logical to indicate whether to facet/wrap a 1d of panels into 2d. By default, it sets FALSE
font.family	the font family for texts
signature	a logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph

Value

an object of class "ggplot" or NULL (if all input pPerf objects are NULL)

Note

none

## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
bp <- xPredictCompare(ls_pPerf, displayBy="ROC")
print(bp)
## modify legend position
bp + theme(legend.position=c(0.75,0.25))

## End(Not run)
```

---

xPredictROCR *Function to assess the prediction performance via ROC and Precision-Recall (PR) analysis*

Description

xPredictROCR is supposed to assess the prediction performance via Receiver Operating Characteristic (ROC) and Precision-Recall (PR) analysis. It requires three inputs: 1) Gold Standard Positive (GSP) targets; 2) Gold Standard Negative (GSN) targets; 3) prediction containing predicted targets and predictive scores.

Usage

```
xPredictROCR(prediction, GSP, GSN, rescale = TRUE, plot = c("none",
"ROC", "PR"), verbose = TRUE, font.family = "sans",
signature = TRUE)
```

Arguments

prediction	a data frame containing predictions along with predictive scores. It has two columns: 1st column for target, 2nd column for predictive scores (the higher the better). Alternatively, it can be an object of class "pNode" (or "sTarget" or "dTarget") from which a data frame is extracted
GSP	a vector containing Gold Standard Positives (GSP)
GSN	a vector containing Gold Standard Negatives (GSN)
rescale	logical to indicate whether to linearly rescale predictive scores for GSP/GSN targets to the range [0,1]. By default, it sets to TRUE
plot	the way to plot performance curve. It can be 'none' for no curve returned, 'ROC' for ROC curve, and 'PR' for PR curve.
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to TRUE for display
font.family	the font family for texts
signature	a logical to indicate whether the signature is assigned to the plot caption. By default, it sets TRUE showing which function is used to draw this graph

Value

If plot is 'none' (by default), an object of class "pPerf", a list with following components:

- PRS: a data frame with 3 columns ('Precision', 'Recall' and 'Specificity')
- AUROC: a scalar value for ROC AUC
- Fmax: a scalar value for maximum F-measure
- ROC_perf: a ROCR performance-class object for ROC curve
- PR_perf: a ROCR performance-class object for PR curve
- Pred_obj: a ROCR prediction-class object (potentially used for calculating other performance measures)

If plot is 'ROC' or 'PR', it will return a ggplot object after being appended with the same components as mentioned above. If no GSP and/or GSN is predicted, it will return NULL

Note

AUC: the area under ROC F-measure: the maximum of a harmonic mean between precision and recall along PR curve

Examples

```
## Not run:
# Load the library
library(Pi)

## End(Not run)
RData.location <- "http://galahad.well.ox.ac.uk/bigdata"
## Not run:
pPerf <- xPredictROCR(prediction, GSP, GSN)

## End(Not run)
```

xRWR *Function to implement Random Walk with Restart (RWR) on the input graph*

Description

xRWR is supposed to implement Random Walk with Restart (RWR) on the input graph. If the seeds (i.e. a set of starting nodes) are given, it intends to calculate the affinity score of all nodes in the graph to the seeds. If the seeds are not given, it will pre-compute affinity matrix for nodes in the input graph with respect to each starting node (as a seed) by looping over every node in the graph. Parallel computing is also supported.

Usage

```
xRWR(g, normalise = c("laplacian", "row", "column", "none"),
setSeeds = NULL, restart = 0.75,
normalise.affinity.matrix = c("none", "quantile"), parallel = TRUE,
multicores = NULL, verbose = TRUE)
```

Arguments

g	an object of class "igraph" or "graphNEL"
normalise	the way to normalise the adjacency matrix of the input graph. It can be 'laplacian' for laplacian normalisation, 'row' for row-wise normalisation, 'column' for column-wise normalisation, or 'none'
setSeeds	an input matrix used to define sets of starting seeds. One column corresponds to one set of seeds that a walker starts with. The input matrix must have row names, coming from node names of input graph, i.e. V(g)$name, since there is a mapping operation. The non-zero entries mean that the corresonding rows (i.e. the gene/row names) are used as the seeds, and non-zero values can be viewed as how to weight the relative importance of seeds. By default, this option sets to "NULL", suggesting each node in the graph will be used as a set of the seed to pre-compute affinity matrix for the input graph. This default does not scale for large input graphs since it will loop over every node in the graph; however, the pre-computed affinity matrix can be extensively reused for obtaining affinity scores between any combinations of nodes/seeds, allows for some flexibility in the downstream use, in particular when sampling a large number of random node combinations for statistical testing
restart	the restart probability used for RWR. The restart probability takes the value from 0 to 1, controlling the range from the starting nodes/seeds that the walker will explore. The higher the value, the more likely the walker is to visit the nodes centered on the starting nodes. At the extreme when the restart probability is zero, the walker moves freely to the neighbors at each step without restarting from seeds, i.e., following a random walk (RW)
normalise.affinity.matrix	the way to normalise the output affinity matrix. It can be 'none' for no normalisation, 'quantile' for quantile normalisation to ensure that columns (if multiple) of the output affinity matrix have the same quantiles

parallel	logical to indicate whether parallel computation with multicores is used. By default, it sets to true, but not necessarily does so. It will depend on whether these two packages "foreach" and "doParallel" have been installed
multicores	an integer to specify how many cores will be registered as the multicore parallel backend to the 'foreach' package. If NULL, it will use a half of cores available in a user's computer. This option only works when parallel computation is enabled
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display

Value

It returns a sparse matrix, called 'PTmatrix':

- When the seeds are NOT given: a pre-computated affinity matrix with the dimension of n X n, where n is the number of nodes in the input graph. Columns stand for starting nodes walking from, and rows for ending nodes walking to. Therefore, a column for a starting node represents a steady-state affinity vector that the starting node will visit all the ending nodes in the graph
- When the seeds are given: an affinity matrix with the dimension of n X nset, where n is the number of nodes in the input graph, and nset for the number of the sets of seeds (i.e. the number of columns in setSeeds). Each column stands for the steady probability vector, storing the affinity score of all nodes in the graph to the starting nodes/seeds. This steady probability vector can be viewed as the "influential impact" over the graph imposed by the starting nodes/seeds.

Note

The input graph will treat as an unweighted graph if there is no 'weight' edge attribute associated with

Examples

```
# 1) generate a random graph according to the ER model
set.seed(123)
g <- erdos.renyi.game(10, 1/10)

## Not run:
# 2) produce the induced subgraph only based on the nodes in query
subg <- dNetInduce(g, V(g), knn=0)
V(subg)$name <- 1:vcount(subg)

# 3) obtain the pre-computated affinity matrix
PTmatrix <- xRWR(g=subg, normalise="laplacian", restart=0.75,
parallel=FALSE)
# visualise affinity matrix
visHeatmapAdv(as.matrix(PTmatrix), Rowv=FALSE, Colv=FALSE,
colormap="wyr", KeyValueName="Affinity")

# 4) obtain affinity matrix given sets of seeds
# define sets of seeds
```

```
# each seed with equal weight (i.e. all non-zero entries are '1')
aSeeds <- c(1,0,1,0,1)
bSeeds <- c(0,0,1,0,1)
setSeeds <- data.frame(aSeeds,bSeeds)
rownames(setSeeds) <- 1:5
# calcualte affinity matrix
PTmatrix <- xRWR(g=subg, normalise="laplacian", setSeeds=setSeeds,
restart=0.75, parallel=FALSE)
PTmatrix

## End(Not run)
```

xVisEvidence *Function to visualise evidence for prioritised genes in a gene network*

Description

xVisEvidence is supposed to visualise evidence for prioritised genes in a gene network. It returns an object of class "igraph".

Usage

```
xVisEvidence(xTarget, g = NA, nodes = NULL, node.info = c("smart",
"none"), neighbor.order = 1, neighbor.seed = TRUE,
neighbor.top = NULL, largest.comp = TRUE, show = TRUE,
colormap = "ggplot2", legend.position = "topleft",
legend.horiz = FALSE, mtext.side = 3, verbose = TRUE,
edge.width = NULL, vertex.size = NULL, vertex.size.nonseed = NULL,
vertex.label.color = "blue", vertex.label.color.nonseed = NULL, ...)
```

Arguments

xTarget	an object of class "dTarget", "sTarget" or "eTarget"
g	an object of class "igraph". If NA, the 'metag' will be used, which is part of the input object "xTarget"
nodes	which node genes are in query. If NULL, the top gene will be queried
node.info	tells the additional information used to label nodes. It can be one of "none" (only gene labeling), "smart" for (by default) using three pieces of information (if any): genes, 5-star ratings, and associated ranks (marked by an @ icon)
neighbor.order	an integer giving the order of the neighborhood. By default, it is 1-order neighborhood
neighbor.seed	logical to indicate whether neighbors are seeds only. By default, it sets to true
neighbor.top	the top number of the neighbors with the highest priority. By default, it sets to NULL to disable this parameter
largest.comp	logical to indicate whether the largest component is only retained. By default, it sets to true for the largest component being left
show	logical to indicate whether to show the graph

colormap	short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta), and "ggplot2" (emulating ggplot2 default color palette). Alternatively, any hyphen-separated HTML color names, e.g. "lightyellow-orange" (by default), "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names
legend.position	the legend position. If NA, the legend is not shown
legend.horiz	logical specifying the legend horizon. If TRUE, set the legend horizontally rather than vertically
mtext.side	the side of marginal text. If NA, it is not shown
verbose	logical to indicate whether the messages will be displayed in the screen. By default, it sets to true for display
edge.width	the width of the edge. If NULL, the width edge is proportional to the 'weight' edge attribute (if existed)
vertex.size	the size of each vertex. If null, each vertex has the size proportional to the degree of nodes
vertex.size.nonseed	the size of each nonseed vertex. If null, each vertex has the size proportional to the degree of nodes
vertex.label.color	the color of vertex labels
vertex.label.color.nonseed	the color of nonseed vertex labels
...	additional graphic parameters. See http://igraph.org/r/doc/plot.common.html for the complete list.

Value

a subgraph, an object of class "igraph".

`xVisEvidenceAdv` *Function to visualise evidence and priority scores for prioritised genes in a gene network*

Description

`xVisEvidenceAdv` is supposed to visualise evidence and priority scores for prioritised genes in a gene network. It returns an object of class "ggplot".

Usage

```
xVisEvidenceAdv(xTarget, g = NA, nodes = NULL, node.info = c("smart",
"none"), neighbor.order = 1, neighbor.seed = TRUE,
neighbor.top = NULL, largest.comp = TRUE, node.label.size = 2,
node.label.color = "black", node.label.alpha = 0.9,
node.label.padding = 0.5, node.label.arrow = 0,
node.label.force = 0.1, node.shape = 19,
node.color.title = "Pi\nrating", colormap = "white-yellow-red",
ncolors = 64, zlim = c(0, 5), node.size.range = 5, title = "",
edge.color = "orange", edge.color.alpha = 0.5, edge.curve = 0,
edge.arrow.gap = 0.025, pie.radius = NULL, pie.color = "black",
pie.color.alpha = 1, pie.thick = 0.1, ...)
```

Arguments

`xTarget`	an object of class "dTarget", "sTarget" or "eTarget"
`g`	an object of class "igraph". If NA, the 'metag' will be used, which is part of the input object "xTarget"
`nodes`	which node genes are in query. If NULL, the top gene will be queried
`node.info`	tells the additional information used to label nodes. It can be one of "none" (only gene labeling), "smart" for (by default) using three pieces of information (if any): genes, 5-star ratings, and associated ranks (marked by an @ icon)
`neighbor.order`	an integer giving the order of the neighborhood. By default, it is 1-order neighborhood
`neighbor.seed`	logical to indicate whether neighbors are seeds only. By default, it sets to true
`neighbor.top`	the top number of the neighbors with the highest priority. By default, it sets to NULL to disable this parameter
`largest.comp`	logical to indicate whether the largest component is only retained. By default, it sets to true for the largest component being left

`node.label.size`
: a vector specifying node size or a character specifying which node attribute used for node label size

`node.label.color`
: the node label color

`node.label.alpha`
: the 0-1 value specifying transparency of node labelling

`node.label.padding`
: the padding around the labeled node

`node.label.arrow`
: the arrow pointing to the labeled node

`node.label.force`
: the repelling force between overlapping labels

`node.shape`
: an integer specifying node shape

`node.color.title`
: a character specifying the title for node coloring

`colormap`
: short name for the colormap. It can be one of "jet" (jet colormap), "bwr" (blue-white-red colormap), "gbr" (green-black-red colormap), "wyr" (white-yellow-red colormap), "br" (black-red colormap), "yr" (yellow-red colormap), "wb" (white-black colormap), "rainbow" (rainbow colormap, that is, red-yellow-green-cyan-blue-magenta), and "ggplot2" (emulating ggplot2 default color palette). Alternatively, any hyphen-separated HTML color names, e.g. "lightyellow-orange" (by default), "blue-black-yellow", "royalblue-white-sandybrown", "darkgreen-white-darkviolet". A list of standard color names can be found in http://html-color-codes.info/color-names

`ncolors`
: the number of colors specified over the colormap

`zlim`
: the minimum and maximum values for which colors should be plotted

`node.size.range`
: the range of actual node size

`title`
: a character specifying the title for the plot

`edge.color`
: a character specifying the edge colors

`edge.color.alpha`
: the 0-1 value specifying transparency of edge colors

`edge.curve`
: a numeric value specifying the edge curve. 0 for the straight line

`edge.arrow.gap`
: a gap between the arrow and the node

`pie.radius`
: the radius of a pie. If NULL, it equals roughly 1/75

`pie.color`
: the border color of a pie

`pie.color.alpha`
: the 0-1 value specifying transparency of pie border colors

`pie.thick`
: the pie border thickness

`...`
: additional graphic parameters for xGGnetwork

Value

a ggplot object.
