Package ‘RBGL’

May 30, 2024

Version 1.80.0
Title An interface to the BOOST graph library
Depends graph, methods
Imports methods
Suggests Rgraphviz, XML, RUnit, BiocGenerics, BiocStyle, knitr
Description A fairly extensive and comprehensive interface to the graph algorithms contained in the BOOST library.
License Artistic-2.0

astarSearch

Compute astarSearch for a graph

Description

Compute astarSearch for a graph

Usage

astarSearch(g)

Arguments

g an instance of the graph class

Details

NOT IMPLEMENTED YET. TO BE FILLED IN

Value

a string indicating non-implementation

Author(s)

Li Long <li.long@isb-sib.ch>

References

Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

Examples

```r
con <- file(system.file("XML/dijkex.gxl",package="RBGL"), open="r")
coex <- fromGXL(con)
close(con)
astarSearch(coex)
```

### bandwidth

**Compute bandwidth for an undirected graph**

#### Description

Compute bandwidth for an undirected graph.

#### Usage

```r
bandwidth(g)
```

#### Arguments

- `g`: an instance of the graph class with `edgemode` "undirected"

#### Details

The bandwidth of an undirected graph $G=(V, E)$ is the maximum distance between two adjacent vertices. See documentation on bandwidth in Boost Graph Library for more details.

#### Value

- `bandwidth`: the bandwidth of the given graph

#### Author(s)

Li Long <li.long@isb-sib.ch>

#### References

- Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

#### Examples

```r
con <- file(system.file("XML/dijkex.gxl",package="RBGL"), open="r")
coex <- fromGXL(con)
close(con)
coex <- ugraph(coex)
bandwidth(coex)
```
Bellman-Ford shortest paths using boost C++

**Description**

Algorithm for the single-source shortest paths problem for a graph with both positive and negative edge weights.

**Usage**

`bellman.ford.sp(g, start=nodes(g)[1])`

**Arguments**

- `g` instance of class graph
- `start` character: node name for start of path

**Details**

This function interfaces to the Boost graph library C++ routines for Bellman-Ford shortest paths. Choose the appropriate algorithm to calculate the shortest path carefully based on the properties of the given graph. See documentation on Bellman-Ford algorithm in Boost Graph Library for more details.

**Value**

A list with elements:

- `all edges minimized` true if all edges are minimized, false otherwise.
- `distance` The vector of distances from `start` to each node of `g`; includes `Inf` when there is no path from `start`.
- `penult` A vector of indices (in `nodes(g)`) of predecessors corresponding to each node on the path from that node back to `start`. For example, if the element one of this vector has value `10`, that means that the predecessor of node `1` is node `10`. The next predecessor is found by examining `penult[10]`.
- `start` The start node that was supplied in the call to `bellman.ford.sp`.

bellman.ford.sp(dd,nodes(dd)[2])

betweenness.centrality.clustering

Graph clustering based on edge betweenness centrality

Description

Graph clustering based on edge betweenness centrality

Usage

betweenness.centrality.clustering(g, threshold = -1, normalize = TRUE)

Arguments

g an instance of the graph class with edgemode "undirected"
threshold threshold to terminate clustering process
normalize boolean, when TRUE, the edge betweenness centrality is scaled by \(2/((n-1)(n-2))\) where \(n\) is the number of vertices in \(g\); when FALSE, the edge betweenness centrality is the absolute value

Details

To implement graph clustering based on edge betweenness centrality.

The algorithm is iterative, at each step it computes the edge betweenness centrality and removes the edge with maximum betweenness centrality when it is above the given threshold. When the maximum betweenness centrality falls below the threshold, the algorithm terminates.

See documentation on Clustering algorithms in Boost Graph Library for details.
bfs

Value
A list of

no.of.edges number of remaining edges after removal
edges remaining edges
degree.betweenness.centrality betweenness centrality of remaining edges

bfs Breadth and Depth-first search

Description
These functions return information on graph traversal by breadth and depth first search using routines from the BOOST library.

Usage
bfs(object, node, checkConn=TRUE)
dfs(object, node, checkConn=TRUE)

Arguments
object instance of class graph from Bioconductor graph class
node node name where search starts; defaults to the node in first position in the node vector.
checkConn logical for backwards compatibility; this parameter has no effect as of RBGL 1.7.9 and will be removed in future versions.
Details

These two functions are interfaces to the BOOST graph library functions for breadth first and depth first search. Both methods handle unconnected graphs by applying the algorithms over the connected components.

Cormen et al note (p 542) that ‘results of depth-first search may depend upon the order in which the vertices are examined ... These different visitation orders tend not to cause problems in practice, as any DFS result can usually be used effectively, with essentially equivalent results’.

Value

For `bfs` a vector of node indices in order of BFS visit.

For `dfs` a list of two vectors of nodes, with elements `discover` (order of DFS discovery), and `finish` (order of DFS completion).

dd <- fromGXL(con1)
close(con1)

bfs(dd, "r")
bfs(dd, "s")

con2 <- file(system.file("XML/dfsex.gxl",package="RBGL"), open="r")
dd2 <- fromGXL(con2)
close(con2)

dfs(dd2, "u")
```

---

`biConnComp`  
Compute biconnected components for a graph

Description

Compute biconnected components for a graph
biConnComp

Usage

biConnComp(g)
articulationPoints(g)

Arguments

g an instance of the graph class

Details

A biconnected graph is a connected graph that remains connected when any one of its vertices, and all the edges incident on this vertex, is removed and the graph remains connected. A biconnected component of a graph is a subgraph which is biconnected. An integer label is assigned to each edge to indicate which biconnected component it’s in.

A vertex in a graph is called an articulation point if removing it increases the number of connected components.

See the documentation for the Boost Graph Library for more details.

Value

For biConnComp: a vector whose length is no. of biconnected components, each entry is a list of nodes that are on the same biconnected components.

For articulationPoints: a vector of articulation points in the graph.

Author(s)

Li Long <li.long@isb-sib.ch>

References

Examples

con <- file(system.file("XML/conn.gxl",package="RBGL"), open="r")
coex <- fromGXL(con)
close(con)

biConnComp(coex)
articulationPoints(coex)
Description

`boyerMyrvoldPlanarityTest` description

Usage

`boyerMyrvoldPlanarityTest(g)`

Arguments

`g` instance of class graphNEL from Bioconductor graph class

Value

logical, TRUE if test succeeds

Author(s)

Li Long <li.long@isb-sib.ch>

References

Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

Examples

```r
con <- file(system.file("XML/dijkex.gxl", package="RBGL"), open="r")
coex <- fromGXL(con)
edgemode(coex) = "undirected"
boyerMyrvoldPlanarityTest(coex) # only shows runnability, need better case
```
brandes.betweenness.centrality

Compute betweenness centrality for an undirected graph

Description

Compute betweenness centrality for an undirected graph

Usage

brandes.betweenness.centrality(g)

Arguments

g an instance of the graph class with edgemode “undirected”

Details

Brandes.betweenness.centrality computes the betweenness centrality of each vertex or each edge in the graph, using an algorithm by U. Brandes.

Betweenness centrality of a vertex $v$ is calculated as follows: $N_{st}(v) =$ no. of shortest paths from $s$ to $t$ that pass through $v$, $N_{st} =$ no. of shortest paths from $s$ to $t$, betweenness centrality of $v$ = $\sum(N_{st}(v)/N_{st})$ for all vertices $s \neq v \neq t$.

Betweenness centrality of an edge is calculated similarly.

The relative betweenness centrality for a vertex is to scale the betweenness centrality of the given vertex by $2/(n**2 - 3n + 2)$ where $n$ is the no. of vertices in the graph.

Central point dominance measures the maximum betweenness of any vertex in the graph.

See documentation on brandes betweenness centrality in Boost Graph Library for more details.

Value

A list of

- betweenness centrality.vertices
  - betweenness centrality of each vertex
- betweenness centrality.edges
  - betweenness centrality of each edge
- relative.betweenness centrality.vertices
  - relative betweenness centrality of each vertex
- dominance
  - maximum betweenness of any point in the graph

g <- addEdge(V[1+3], V[0+1], g)
g <- addEdge(V[1+3], V[4+1], g)
g <- addEdge(V[1+4], V[5+1], g)
g <- addEdge(V[1+5], V[6+1], g)
g <- addEdge(V[1+6], V[3+1], g)
g <- addEdge(V[1+0], V[4+1], g)
g <- addEdge(V[1+1], V[3+1], g)
g <- addEdge(V[1+3], V[5+1], g)
g <- addEdge(V[1+2], V[6+1], g)
g <- addEdge(V[1+1], V[4+1], g)
g <- addEdge(V[1+1], V[5+1], g)
g <- addEdge(V[1+1], V[6+1], g)

x3 <- chrobakPayneStraightLineDrawing(g)
x3
plot(t(x3))
el = edgeL(g)
for (i in seq_len(length(nodes(g))))
  segments(
    rep(x3["x",i], length(el[[i]]$edges)),
    rep(x3["y",i], length(el[[i]]$edges)),
    x3["x", nodes(g)[el[[i]]$edges]],
    x3["y", nodes(g)[el[[i]]$edges]]
  )
```

---

**clusteringCoef**  
*Calculate clustering coefficient for an undirected graph*

**Description**

Calculate clustering coefficient for an undirected graph

**Usage**

```r
clusteringCoef(g, Weighted=FALSE, vW=degree(g))
```

**Arguments**

- `g` an instance of the graph class
- `Weighted` calculate weighted clustering coefficient or not
- `vW` vertex weights to use when calculating weighted clustering coefficient
Details

For an undirected graph $G$, let $\delta(v)$ be the number of triangles with $v$ as a node, let $\tau(v)$ be the number of triples, i.e., paths of length 2 with $v$ as the center node.

Let $V'$ be the set of nodes with degree at least 2.

Define clustering coefficient for $v$, $c(v) = (\delta(v) / \tau(v))$.

Define clustering coefficient for $G$, $C(G) = \frac{\sum c(v)}{|V'|}$, for all $v$ in $V'$.

Define weighted clustering coefficient for $G$, $C_w(G) = \frac{\sum w(v) * c(v)}{\sum w(v)}$, for all $v$ in $V'$.

Value

Clustering coefficient for graph $G$.

Author(s)

Li Long <li.long@isb-sib.ch>

References

See Also

clusteringCoefAppr, transitivity, graphGenerator

Examples

```r
con <- file(system.file("XML/conn.gxl",package="RBGL"))
g <- fromGXL(con)
close(con)
c <- clusteringCoef(g)
c <- clusteringCoef(g, Weighted=TRUE)
vW <- c(1, 1, 1, 1, 1, 1, 1)
c <- clusteringCoef(g, Weighted=TRUE, vW)
```

---

**clusteringCoefAppr**  
*Approximate clustering coefficient for an undirected graph*

Description

Approximate clustering coefficient for an undirected graph

Usage

```r
clusteringCoefAppr(g, k=length(nodes(g)), Weighted=FALSE, vW=degree(g))
```
Arguments

- \textbf{g}: an instance of the graph class
- \textbf{Weighted}: calculate weighted clustering coefficient or not
- \textbf{vW}: vertex weights to use when calculating weighted clustering coefficient
- \textbf{k}: parameter controls total expected runtime

Details

It is quite expensive to compute cluster coefficient and transitivity exactly for a large graph by computing the number of triangles in the graph. Instead, \texttt{clusteringCoefAppr} samples triples with appropriate probability, returns the ratio between the number of existing edges and the number of samples.

MORE ABOUT CHOICE OF K.

See reference for more details.

Value

Approximated clustering coefficient for graph \texttt{g}.

Author(s)

Li Long <li.long@isb-sib.ch>

g <- fromGXL(con)
close(con)

k = length(nodes(g))
cc <- clusteringCoefAppr(g, k)
ccw1 <- clusteringCoefAppr(g, k, Weighted=TRUE)
vW <- c(1, 1, 1, 1, 1, 1, 1, 1)
ccw2 <- clusteringCoefAppr(g, k, Weighted=TRUE, vW)
```
connectedComp

Identify Connected Components in an Undirected Graph

Description
The connected components in an undirected graph are identified. If the graph is directed then the weakly connected components are identified.

Usage
connectedComp(g)

Arguments
g graph with edgemode "undirected"

Details
Uses a depth first search approach to identifying all the connected components of an undirected graph. If the input, g, is a directed graph it is first transformed to an undirected graph (using ugraph).

Value
A list of length equal to the number of connected components in g. Each element of the list contains a vector of the node labels for the nodes that are connected.

Author(s)
Vince Carey <stvjc@channing.harvard.edu>

References

ukm
edges(ukm)
connectedComp(ukm)

dag.sp

**DAG shortest paths using boost C++**

Description

Algorithm for the single-source shortest-paths problem on a weighted, directed acyclic graph (DAG)

Usage

dag.sp(g,start=nodes(g)[1])

Arguments

g instance of class graph

start source node for start of paths

Details

These functions are interfaces to the Boost graph library C++ routines for single-source shortest-paths on a weighted directed acyclic graph. Choose appropriate shortest-path algorithms carefully based on the properties of the input graph. See documentation in Boost Graph Library for more details.

Value

A list with elements:

distance The vector of distances from start to each node of g; includes Inf when there is no path from start.

penult A vector of indices (in nodes(g)) of predecessors corresponding to each node on the path from that node back to start. For example, if the element one of this vector has value 10, that means that the predecessor of node 1 is node 10. The next predecessor is found by examining penult[10].

start The start node that was supplied in the call to dag.sp.
Author(s)

Li Long <li.long@isb-sib.ch>

References

bellman.ford.sp, dijkstra.sp, johnson.all.pairs.sp, sp.between

Examples

```r
con <- file(system.file("XML/conn2.gxl",package="RBGL"), open="r")
dd <- fromGXL(con)
close(con)
dag.sp(dd)
dag.sp(dd,nodes(dd)[2])
```

dijkstra.sp

Dijkstra’s shortest paths using boost C++

Description

dijkstra’s shortest paths

Usage

dijkstra.sp(g,start=nodes(g)[1], eW=unlist(edgeWeights(g)))

Arguments

g
start
eW

numeric: edge weights.

Details

These functions are interfaces to the Boost graph library C++ routines for Dijkstra’s shortest paths. For some graph subclasses, computing the edge weights can be expensive. If you are calling dijkstra.sp in a loop, you can pass the edge weights explicitly to avoid the edge weight creation cost.
dijkstra.sp

Value

A list with elements:

- **distance**: The vector of distances from start to each node of g; includes Inf when there is no path from start.

- **penult**: A vector of indices (in nodes(g)) of predecessors corresponding to each node on the path from that node back to start.

  For example, if the element one of this vector has value 10, that means that the predecessor of node 1 is node 10. The next predecessor is found by examining penult[10].

- **start**: The start node that was supplied in the call to dijkstra.sp.

dijkstra.sp(dd, nodes(dd)[2])

c2 <- file(system.file("XML/ospf.gxl", package="RBGL"), open="r")
ospf <- fromGXL(c2)
close(c2)
dijkstra.sp(ospf, nodes(ospf)[6])
```
dominatorTree

Compute dominator tree from a vertex in a directed graph

dominateTree

Description

Compute dominator tree from a vertex in a directed graph

Usage

dominatorTree(g, start=nodes(g)[1])
lengauerTarjanDominatorTree(g, start=nodes(g)[1])

Arguments

- `g`  
a directed graph, one instance of the graph class
- `start`  
a vertex in graph `g`

Details

As stated in documentation on Lengauer Tarjan dominator tree in Boost Graph Library:
A vertex `u` dominates a vertex `v`, if every path of directed graph from the entry to `v` must go through `u`.
This function builds the dominator tree for a directed graph.

Value

Output is a vector, giving each node its immediate dominator.

Examples

col <- file(system.file("XML/dominator.gxl",package="RBGL"), open="r")
gl <- fromGXL(col)
close(col)

dominatorTree(gl)
lengauerTarjanDominatorTree(gl)
Description

computed edge connectivity and min disconnecting set for an undirected graph

Usage

desConnectivity(g)

Arguments

g an instance of the graph class with edgemode “undirected”

Details

Consider a graph G consisting of a single connected component. The edge connectivity of G is the minimum number of edges in G that can be cut to produce a graph with two (disconnected) components. The set of edges in this cut is called the minimum disconnecting set.

Value

A list:

connectivity the integer describing the number of edges that must be severed to obtain two components

minDisconSet a list (of length connectivity) of pairs of node names describing the edges that need to be cut to obtain two components

extractPath

convert a dijkstra.sp predecessor structure into the path joining two nodes

description

determine a path between two nodes in a graph, using output of dijkstra.sp.

Usage

extractPath(s, f, pens)

Arguments

s

index of starting node in nodes vector of the graph from which pens was derived

f

index of ending node in nodes vector

pens

predecessor index vector as returned in the preds component of dijkstra.sp output

Value

numeric vector of indices of nodes along shortest path

compute shortest paths for all pairs of nodes

Description
compute shortest paths for all pairs of nodes

Usage
floyd.warshall.all.pairs.sp(g)

Arguments

g graph object with edge weights given

Details
Compute shortest paths between every pair of vertices for a dense graph. It works on both undirected and directed graph. The result is given as a distance matrix. The matrix is symmetric for an undirected graph, and asymmetric (very likely) for a directed graph. For a sparse graph, the johnson.all.pairs.sp functions should be used instead.

See documentation on these algorithms in Boost Graph Library for more details.

Value
A matrix of shortest path lengths between all pairs of nodes in the graph.

gprofile  Compute profile for a graph

Description
Compute profile for a graph

Usage
gprofile(g)

Arguments
  g     an instance of the graph class

Details
The profile of a given graph is the sum of bandwidths for all the vertices in the graph.
See documentation on this function in Boost Graph Library for more details.

Value
  profile        the profile of the graph

graphGenerator

Generate an undirected graph with adjustable clustering coefficient

Description
Generate an undirected graph with adjustable clustering coefficient

Usage
graphGenerator(n, d, o)

Arguments
n  no. of nodes in the generated graph
d  parameter for preferential attachment
o  parameter for triple generation

Details
The graph generator works according to the preferential attachment rule. It also generates graphs with adjustable clustering coefficient. Parameter d specifies how many preferred edges a new node has. Parameter o limits how many triples to add to a new node.
See reference for details.

Value

no. of nodes  No. of nodes in the generated graph
no. of edges  No. of edges in the generated graph
edges        Edges in the generated graph

o <- 3
gg <- graphGenerator(n, d, o)
\end{verbatim}

Description

Compute highly connected subgraphs for an undirected graph

Usage

highlyConnSG(g, sat=3, ldv=c(3,2,1))

Arguments

- **g**: an instance of the graph class with edgemode "undirected"
- **sat**: singleton adoption threshold, positive integer
- **ldv**: heuristics to remove lower degree vertex, a decreasing sequence of positive integer

Details

A graph G with n vertices is highly connected if its connectivity k(G) > n/2. The HCS algorithm partitions a given graph into a set of highly connected subgraphs, by using minimum-cut algorithm recursively. To improve performance, the approach is refined by adopting singletons, removing low degree vertices and merging clusters.

On singleton adoption: after each round of partition, some highly connected subgraphs could be singletons (i.e., a subgraph contains only one node). To reduce the number of singletons, therefore reduce number of clusters, we try to get "normal" subgraphs to "adopt" them. If a singleton, s, has n neighbours in a highly connected subgraph c, and n > sat, we add s to c. To adapt to the modified subgraphs, this adoption process is repeated until no further such adoption.

On lower degree vertices: when the graph has low degree vertices, minimum-cut algorithm will just repeatedly separate these vertices from the rest. To reduce such expensive and non-informative computation, we "remove" these low degree vertices first before applying minimum-cut algorithm. Given ldv = (d1, d2, ..., dp), (d[i] > d[i+1] > 0), we repeat the following (i from 1 to p): remove all the highly-connected-subgraph found so far; remove vertices with degrees < di; find highly-connected-subgraphs; perform singleton adoptions.

The Boost implementation does not support self-loops, therefore we signal an error and suggest that users remove self-loops using the function removeSelfLoops function. This change does affect degree, but the original article makes no specific reference to self-loops.
incremental.components

Value
A list of clusters, each is given as vertices in the graph.

Author(s)
Li Long <li.long@isb-sib.ch>

highlyConnSG(coex)

incremental.components
Compute connected components for an undirected graph

Description
Compute connected components for an undirected graph

Usage
init.incremental.components(g)
incremental.components(g)
same.component(g, node1, node2)

Arguments

g an instance of the graph class
node1 one vertex of the given graph
node2 another vertex of the given graph
Details

This family of functions work together to calculate the connected components of an undirected graph. The algorithm is based on the disjoint-sets. It works where the graph is growing by adding new edges. Call "init.incremental.components" to initialize the calculation on a new graph. Call "incremental.components" to re-calculate connected components after growing the graph. Call "same.component" to learn if two given vertices are in the same connected components. Currently, the codes can only handle ONE incremental graph at a time. When you start working on another graph by calling "init.incremental.components", the disjoint-sets info on the previous graph is lost. See documentation on Incremental Connected Components in Boost Graph Library for more details.

Value

Output from init.incremental.components is a list of component numbers for each vertex in the graph.

Output from incremental.components is a list of component numbers for each vertex in the graph.

Output from same.component is true if both nodes are in the same connected component, otherwise it's false.

v1 <- 1
v2 <- 5
same.component(coex, v1, v2)
is.triangulated  

**Description**

Decide if a graph is triangulated

**Usage**

\[
\text{is.triangulated}(g)
\]

**Arguments**

- \(g\) an instance of the graph class

**Details**

An undirected graph \(G = (V, E)\) is triangulated (i.e. chordal) if all cycles \([v_1, v_2, ..., v_k]\) of length 4 or more have a chord, i.e., an edge \([v_i, v_j]\) with \(j \neq i \pm 1 \text{ (mod k)}\)

An equivalent definition of chordal graphs is:

- \(G\) is chordal iff either \(G\) is an empty graph, or there is an \(v\) in \(V\) such that
  1. the neighborhood of \(v\) (i.e., \(v\) and its adjacent nodes) forms a clique, and
  2. recursively, \(G-v\) is chordal

**Value**

The return value is \(\text{TRUE}\) if \(g\) is triangulated and \(\text{FALSE}\) otherwise. An error is thrown if the graph is not undirected; you might use \(\text{ugraph}\) to compute the underlying graph.

---

**isomorphism**

Compute isomorphism from vertices in one graph to those in another graph

**Description**

Compute isomorphism from vertices in one graph to those in another graph

**Usage**

```r
isomorphism(g1, g2)
```

**Arguments**

- `g1`: one instance of the `graph` class
- `g2`: one instance of the `graph` class

**Details**

As stated in documentation on isomorphism in Boost Graph Library: An isomorphism is a 1-to-1 mapping of the vertices in one graph to the vertices of another graph such that adjacency is preserved. Another words, given graphs G1 = (V1,E1) and G2 = (V2,E2) an isomorphism is a function f such that for all pairs of vertices a,b in V1, edge (a,b) is in E1 if and only if edge (f(a),f(b)) is in E2.

**Value**

Output is true if there exists an isomorphism between `g1` and `g2`, otherwise it's false.

kCliques

Find all the k-cliques in an undirected graph

Description
Find all the k-cliques in an undirected graph

Usage
kCliques(g)

Arguments
g an instance of the graph class

Details
Notice that there are different definitions of k-clique in different context.
In computer science, a k-clique of a graph is a clique, i.e., a complete subgraph, of k nodes.
In Social Network Analysis, a k-clique in a graph is a subgraph where the distance between any two nodes is no greater than k.
Here we take the definition in Social Network Analysis.
Let D be a matrix, D[i][j] is the shortest path from node i to node j. Algorithm is outlined as following: (1) use Johnson’s algorithm to fill D; let N = max(D[i][j]) for all i, j; (2) each edge is a
1-clique by itself; (3) for \( k = 2, \ldots, N \), try to expand each \((k-1)\)-clique to \( k \)-clique: (3.1) consider a \((k-1)\)-clique the current \( k \)-clique \( K_C \); (3.2) repeat the following: if for all nodes \( j \) in \( K_C \), \( D[v][j] \leq k \), add node \( v \) to \( K_C \); (3.3) eliminate duplicates; (4) the whole graph is \( N \)-clique.

Value

A list of length \( N \); \( k \)-th entry (\( k = 1, \ldots, N \)) is a list of all the \( k \)-cliques in graph \( g \).

Author(s)

Li Long <li.long@isb-sib.ch>

References

Examples

```r
con <- file(system.file("XML/snacliqueex.gxl",package="RBGL"))
coex <- fromGXL(con)
close(con)
kCliques(coex)
```

**kCores**

Find all the \( k \)-cores in a graph

Description

Find all the \( k \)-cores in a graph

Usage

```r
kCores(g, EdgeType=c("in", "out"))
```

Arguments

- \( g \) an instance of the graph class
- \( \text{EdgeType} \) what types of edges to be considered when \( g \) is directed

Details

A \( k \)-core in a graph is a subgraph where each node is adjacent to at least a minimum number, \( k \), of the other nodes in the subgraph.

A \( k \)-core in a graph may not be connected.

The core number for each node is the highest \( k \)-core this node is in. A node in a \( k \)-core will be, by definition, in a \((k-1)\)-core.

The implementation is based on the algorithm by V. Batagelj and M. Zaversnik, 2002.

The example snacoreex.gxl is in the paper by V. Batagelj and M. Zaversnik, 2002.
Value

A vector of the core numbers for all the nodes in g.

```

---

**lambdaSets**

*Find all the lambda-sets in an undirected graph*

Description

Find all the lambda-sets in an undirected graph

Usage

`lambdaSets(g)`

Arguments

- `g` an instance of the graph class
Details

From reference (1), p. 270: A set of nodes is a lambda-set if any pair of nodes in the lambda set has larger edge connectivity than any pair of nodes consisting of one node from within the lambda set and a second node from outside the lambda set.

As stated in reference (2), a lambda set is a maximal subset of nodes who have more edge-independent paths connecting them to each other than to outsiders.

A lambda set could be characterized by the minimum edge connectivity $k$ among its members, and could be called $\lambda_k$ sets.

Let $N$ be maximum edge connectivity of graph $g$, we output all the lambda-$k$ set for all $k = 1, ..., N$.

Value

Maximum edge connectivity, $N$, of the graph $g$, and A list of length $N$; $k$-th entry ($k = 1, ..., N$) is a list of all the lambda-$k$ sets in graph $g$.

Author(s)

Li Long <li.long@isb-sib.ch>

con <- file(system.file("XML/snalambdaex.gxl",package="RBGL"))
coex <- fromGXL(con)
close(con)

lambdaSets(coex)
```

layout

Layout an undirected graph in 2D – suspended june 16 2012

Description

Layout an undirected graph in 2D – suspended june 16 2012

Usage

```r
circleLayout(g, radius=1) # does not compile with boost 1.49
kamadaKawaiSpringLayout( g, edge_or_side=1, es_length=1 )
fruchtermanReingoldForceDirectedLayout(g, width=1, height=1)
randomGraphLayout(g, minX=0, maxX=1, minY=0, maxY=1)
```
Arguments

- **g**: an instance of the graph class with `edgemode` "undirected"
- **radius**: radius of a regular n-polygon
- **edge_or_side**: boolean indicating the length is for an edge or for a side, default is for an edge
- **es_length**: the length of an edge or a side for layout
- **width**: the width of the display area, all x coordinates fall in [-width/2, width/2]
- **height**: the height of the display area, all y coordinates fall in [-height/2, height/2]
- **minX**: minimum x coordinate
- **maxX**: maximum x coordinate
- **minY**: minimum y coordinate
- **maxY**: maximum y coordinate

Details

If you want to simply draw a graph, you should consider using package `Rgraphviz`. The layout options in package `Rgraphviz`: `neato`, `circo` and `fdp`, correspond to `kamadaKawaiSpringLayout`, `circleLayout` and `fruchtermanReingoldForceDirectedLayout`, respectively.

Function `circleLayout` layouts the graph with the vertices at the points of a regular n-polygon. The distance from the center of the polygon to each point is determined by the `radius` parameter.

Function `kamadaKawaiSpringLayout` provides Kamada-Kawai spring layout for connected, undirected graphs. User provides either the unit length `e` of an edge in the layout or the length of a side `s` of the display area.

Function `randomGraphLayout` places the points of the graph at random locations.

Function `fruchtermanReingoldForceDirectedLayout` performs layout of unweighted, undirected graphs. It's a force-directed algorithm. The BGL implementation doesn't handle disconnected graphs very well, since it doesn't explicitly give each connected component a region proportional to its size.

See documentation on this function in Boost Graph Library for more details.

Value

A (2 x n) matrix, where n is the number of nodes in the graph, each column gives the (x, y)-coordinates for the corresponding node.

### Description

`makeBiconnectedPlanar` description

### Usage

```r
makeBiconnectedPlanar(g)
```

### Arguments

- **g**: instance of class `graphNEL` from Bioconductor graph class

### Details

From [http://www.boost.org/doc/libs/1_49_0/libs/graph/doc/planar_graphs.html](http://www.boost.org/doc/libs/1_49_0/libs/graph/doc/planar_graphs.html)

An undirected graph is connected if, for any two vertices u and v, there's a path from u to v. An undirected graph is biconnected if it is connected and it remains connected even if any single vertex is removed. Finally, a planar graph is maximal planar (also called triangulated) if no additional edge (with the exception of self-loops and parallel edges) can be added to it without creating a non-planar graph. Any maximal planar simple graph on \( n > 2 \) vertices has exactly \( 3n - 6 \) edges and \( 2n - 4 \) faces, a consequence of Euler's formula. If a planar graph isn't connected, isn't biconnected, or

### Examples

```r
## Not run:
con <- file(system.file("XML/conn.gxl", package="RBGL"), open="r")
coex <- fromGXL(con)
close(con)
coex <- ugraph(coex)
circleLayout(coex)
kamadaKawaiSpringLayout(coex)
randomGraphLayout(coex)
fruchtermanReingoldForceDirectedLayout(coex, 10, 10)
## End(Not run)
```
isn’t maximal planar, there is some set of edges that can be added to the graph to make it satisfy any of those three properties while preserving planarity. Many planar graph drawing algorithms make at least one of these three assumptions about the input graph, so there are functions in the Boost Graph Library that can help:

make_connected adds a minimal set of edges to an undirected graph to make it connected.

make_biconnected_planar adds a set of edges to a connected, undirected planar graph to make it biconnected while preserving planarity.

make_maximal_planar adds a set of edges to a biconnected, undirected planar graph to make it maximal planar.

The function documented here implements the second approach.

Value

A list with two elements: ‘Is planar’ is a logical indicating achievement of planarity, and ‘new graph’, a graphNEL instance that is biconnected and planar.

max.flow

Compute max flow for a directed graph

Description

Compute max flow for a directed graph

Usage

edmonds.karp.max.flow(g, source, sink)
push.relabel.max.flow(g, source, sink)
kolmogorov.max.flow(g, source, sink)

Arguments

g: an instance of the graph class with edgemode “directed”
source: node name (character) or node number (int) for the source of the flow
sink: node name (character) or node number (int) for the sink of the flow

Details

Given a directed graph G=(V,E) of a single connected component with a vertex source and a vertex sink. Each arc has a positive real valued capacity, currently it’s equivalent to the weight of the arc. The flow of the network is the net flow entering the vertex sink. The maximum flow problem is to determine the maximum possible value for the flow to the sink and the corresponding flow values for each arc.

See documentation on these algorithms in Boost Graph Library for more details.

Value

A list of

maxflow: the max flow from source to sink
edges: the nodes of the arcs with non-zero capacities
flows: the flow values of the arcs with non-zero capacities

Li Long <li.long@isb-sib.ch>
maxClique

Find all the cliques in a graph

Description
Find all the cliques in a graph

Usage
maxClique(g, nodes=NULL, edgeMat=NULL)

Arguments
  g              an instance of the graph class
  nodes          vector of node names, to be supplied if g is not
  edgeMat        2 x p matrix with indices of edges in nodes, one-based, only to be supplied if
codeg is not

  minCut, edgeConnectivity

Examples
con <- file(system.file("XML/dijkex.gxl", package="RBGL"), open="r")
g <- fromGXL(con)
close(con)

ans1 <- edmonds.karp.max.flow(g, "B", "D")
ans2 <- edmonds.karp.max.flow(g, 3, 2)  # 3 and 2 equivalent to "C" and "B"
ans3 <- push.relabel.max.flow(g, 2, 4)  # 2 and 4 equivalent to "B" and "D"
ans4 <- push.relabel.max.flow(g, "C", "B")

# error in the following now, 14 June 2014
#ans5 <- kolmogorov.max.flow(g, "B", "D")
#ans6 <- kolmogorov.max.flow(g, 3, 2)
maximumCycleRatio

Details

Notice the maximum clique problem is NP-complete, which means it cannot be solved by any known polynomial algorithm.

We implemented the algorithm by C. Bron and J. Kerbosch.

It is an error to supply both \( g \) and either of the other arguments.

If \( g \) is not supplied, no checking of the consistency of nodes and edgeMat is performed.

Value

- \( \text{maxClique} \) list of all cliques in \( g \)

Usage

maximumCycleRatio(g)

Arguments

- \( g \) instance of class graphNEL from Bioconductor graph class
### Details

NOT IMPLEMENTED

### Value

A list with message indicating not implemented

### Author(s)

Li Long <li.long@isb-sib.ch>

### References

- Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

---

### Description

Compute min-cut for an undirected graph

### Usage

```minCut(g)```

### Arguments

- `g` an instance of the `graph` class with edgemode “undirected”

### Details

Given an undirected graph $G=(V, E)$ of a single connected component, a cut is a partition of the set of vertices into two non-empty subsets $S$ and $V-S$, a cost is the number of edges that are incident on one vertex in $S$ and one vertex in $V-S$. The min-cut problem is to find a cut $(S, V-S)$ of minimum cost.

For simplicity, the returned subset $S$ is the smaller of the two subsets.

### Value

A list of

- `mincut` the number of edges to be severed to obtain the minimum cut
- `S` the smaller subset of vertices in the minimum cut
- `V-S` the other subset of vertices in the minimum cut

mstree.kruskal  Kruskal’s minimum spanning tree in boost

Description

compute the minimum spanning tree (MST) for a graph and return a representation in matrices

Usage

mstree.kruskal(x)

Arguments

x  instance of class graph

Details

calls to kruskal minimum spanning tree algorithm of Boost graph library

Value

a list

edgeList  a matrix m of dimension 2 by number of edges in the MST, with m[i,j] the jth node in edge i

weights  a vector of edge weights corresponding to the columns of edgeList

nodes  the vector of nodes of the input graph x

Author(s)

VJ Carey <stvjc@channing.harvard.edu>

References

print(sum(m[[2]]))
```

---

**mstree.prim**  
*Compute minimum spanning tree for an undirected graph*

**Description**

Compute minimum spanning tree for an undirected graph

**Usage**

```r
mstree.prim(g)
```

**Arguments**

- `g`: an instance of the graph class with edgemode “undirected”

**Details**

This is Prim’s algorithm for solving the minimum spanning tree problem for an undirected graph with weighted edges.

See documentations on this function in Boost Graph Library for more details.

**Value**

A list of:
- `edges`: the edges that form the minimum spanning tree
- `weights`: the total weight of the minimum spanning tree

**Author(s)**

Li Long <li.long@isb-sib.ch>
**Ordering**

**Compute vertex ordering for an undirected graph**

**Description**

Compute vertex ordering for an undirected graph

**Usage**

```r
cuthill.mckee.ordering(g)
minDegreeOrdering(g, delta=0)
sloan.ordering(g, w1=1, w2=2)
```

**Arguments**

- `g`: an instance of the graph class with edgemode “undirected”
- `delta`: Multiple elimination control variable. If it is larger than or equal to zero then multiple elimination is enabled. The value of `delta` specifies the difference between the minimum degree and the degree of vertices that are to be eliminated.
- `w1`: First heuristic weight for the Sloan algorithm.
- `w2`: Second heuristic weight for the Sloan algorithm.

**Examples**

```r
con <- file(system.file("XML/conn2.gxl",package="RBGL"))
coex <- fromGXL(con)
close(con)

mstree.prim(coex)
```
Details

The following details were obtained from the documentation of these algorithms in Boost Graph Library and readers are referred their for even more detail. The goal of the Cuthill-Mckee (and reverse Cuthill-McKee) ordering algorithm is to reduce the bandwidth of a graph by reordering the indices assigned to each vertex.

The minimum degree ordering algorithm is a fill-in reduction matrix reordering algorithm.

The goal of the Sloan ordering algorithm is to reduce the profile and the wavefront of a graph by reordering the indices assigned to each vertex.

The goal of the King ordering algorithm is to reduce the bandwidth of a graph by reordering the indices assigned to each vertex.

Value

cuthill.mckee.ordering
returns a list with elements:
reverse cuthill.mckee.ordering
the vertices in the new ordering
original bandwidth
bandwidth before reordering vertices
new bandwidth
bandwidth after reordering of vertices
minDegreeOrdering
return a list with elements:
inverse_permutation
the new vertex ordering, given as the mapping from the new indices to the old indices
permutation
the new vertex ordering, given as the mapping from the old indices to the new indices
sloan.ordering
returns a list with elements:
sloan.ordering
the vertices in the new ordering
bandwidth
bandwidth of the graph after reordering
profile
profile of the graph after reordering
maxWavefront
maxWavefront of the graph after reordering
aver.wavefront
aver.wavefront of the graph after reordering
rms.wavefront
rms.wavefront of the graph after reordering

**RBGL-defunct**

*Defunct Functions in Package RBGL*

**Description**

The functions or variables listed here are no longer part of the RBGL package.

**Usage**

prim.minST()

**Value**

none

**See Also**

Defunct
Description

The RBGL package consists of a number of interfaces to the Boost C++ library for graph algorithms. This page follows, approximately, the chapter structure of the monograph on the Boost Graph Library by Siek et al., and gives hyperlinks to documentation on R functions currently available, along with the names of formal parameters to these functions.

Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

**Description**

remove self loops in a graph

**Usage**

```r
removeSelfLoops(g)
```

**Arguments**

- `g` one instance of the graph class

**Details**

If a given graph contains self-loop(s), `removeSelfLoops` removes them. This is for those functions that cannot handle graphs with self-loops.

**Value**

A new graph without self loops.

**Author(s)**

Li Long <li.long@isb-sib.ch>

**Examples**

```r
con <- file(system.file("XML/dijkex.gxl", package="RBGL"))
g1 <- fromGXL(con)
close(con)

g2 <- ugraph(g1)
removeSelfLoops(g2)
```
separates A function to test whether a subset of nodes separates two other subsets of nodes.

Description

The function tests to see whether a set of nodes, S1, separates all nodes in a from all nodes in b.

Usage

separates(a, b, S1, g)

Arguments

a The names of the nodes in the from set.
b The names of the nodes in the to set.
S1 The names of the nodes in the separation set.
g An instance of the graph class. All nodes named in the other arguments must be nodes of this graph.

Details

The algorithm is quite simple. A subgraph is created by removing the nodes named in S1 from g. Then all paths between elements of a to elements of b are tested for. If any path exists the function returns FALSE, otherwise it returns TRUE.

Value

Either TRUE or FALSE depending on whether S1 separates a from b in g1.

c <- file(system.file("XML/kmstEx.gxl",package="RBGL"))
k <- fromGXL(c)
close(c)

separates("B", "A", "E", k)
separates("B", "A", "C", k)
```

sequential.vertex.coloring

*Compute a vertex coloring for a graph*

Description

Compute vertex coloring for a graph

Usage

```r
sequential.vertex.coloring(g)
```

Arguments

- `g` an instance of the graph class

Details

A vertex coloring for a graph is to assign a color for each vertex so that no two adjacent vertices are of the same color. We designate the colors as sequential integers: 1, 2, ....

For ordered vertices, v1, v2, ..., vn, for k = 1, 2, ..., n, this algorithm assigns vk to the smallest possible color. It does NOT guarantee to use minimum number of colors.

See documentations on these algorithms in Boost Graph Library for more details.

Value

- no. of colors needed
  - how many colors to use to color the graph
- colors of nodes
  - color label for each vertex

Author(s)

Li Long <li.long@isb-sib.ch>

References

- Boost Graph Library (www.boost.org/libs/graph/doc/index.html)
Examples

Boost Graph Library (www.boost.org/libs/graph/doc/index.html)

**sp.between**  
*Dijskstra’s shortest paths using boost C++*

---

**Description**

Dijkstra’s shortest paths

**Usage**

```r
sp.between(g, start, finish, detail=TRUE)
```

**Arguments**

- **g**: instance of class graph
- **start**: node name(s) for start of path(s)
- **finish**: node name(s) for end of path(s)
- **detail**: if TRUE, output additional info on the shortest path

**Details**

These functions are interfaces to the Boost graph library C++ routines for Dijkstra’s shortest paths. Function `sp.between.scalar` is obsolete.

**Value**

When `start` and/or `finish` are vectors, we use the normal cycling rule in R to match both vectors and try to find the shortest path for each pair.

Function `sp.between` returns a list of info on the shortest paths. Each such shortest path is designated by its starting node and its ending node. Each element in the returned list contains:

- **length**: total length (using edge weights) of this shortest path
- **path_detail**: if requested, a vector of names of the nodes on the shortest path
- **length_detail**: if requested, a list of edge weights of this shortest path

See `pathWeights` for caveats about undirected graph representation.

# see NAs for query on nonexistent path
sp.between(ospf, "N10", "N13")

strongComp

Identify Strongly Connected Components

Description

The strongly connected components in a directed graph are identified and returned as a list.

Usage

strongComp(g)

Arguments

g graph with edgemode "directed".

Details

Tarjan’s algorithm is used to determine all strongly connected components of a directed graph.

Value

A list whose length is the number of strongly connected components in g. Each element of the list is a vector of the node labels for the nodes in that component.

transitive.closure Compute transitive closure of a directed graph

Description
Compute transitive closure of a directed graph

Usage
transitive.closure(g)

Arguments
g an instance of the graph class

Details
This function calculates the transitive closure of a directed graph. See documentation on this function in Boost Graph Library for more details.

Value
An object of class graphNEL.

transitivity

Calculate transitivity for an undirected graph

Description
Calculate transitivity for an undirected graph

Usage
transitivity(g)

Arguments
g an instance of the graph class

Details
For an undirected graph G, let delta(v) be the number of triangles with v as a node, let tau(v) be the number of triples, i.e., paths of length 2 with v as the center node.
Define transitivity T(G) = sum(delta(v)) / sum(tau(v)), for all v in V.

Value
Transitivity for graph g.

tsort

topological sort of vertices of a digraph

Description

returns vector of zero-based indices of vertices of a DAG in topological sort order

Usage

tsort(x) # now x assumed to be Bioconductor graph graphNEL

Arguments

x

instance of class graphNEL from Bioconductor graph class

Details

calls to the topological_sort algorithm of BGL, will check in BGL whether the input is a DAG and return a vector of zeroes (of length length(nodes(x))) if it is not. Thus this function can be used to check for cycles in a digraph.

Value

A character vector of vertices in the topological sort sequence.

Author(s)
