Package ‘tweeDEseq’

November 3, 2016

Type Package

Title RNA-seq data analysis using the Poisson-Tweedie family of distributions

Version 1.20.0

Depends R (>= 2.12.0)

Imports MASS, limma, edgeR, parallel, cqn

Suggests tweeDEseqCountData, xtable

Author Juan R Gonzalez <jrgonzalez@creal.cat> and Mikel Esnaola<br>
<mesnaola@creal.cat> (with contributions from Robert Castelo<br>
<robert.castelo@upf.edu>)

Maintainer Juan R Gonzalez <jrgonzalez@creal.cat>

Description Differential expression analysis of RNA-seq using the Poisson-Tweedie family of distributions.

**compareCountDist**

**Description**

Compares the empirical and estimated distributions for different count data models.

**Usage**

```r
compareCountDist(x, plot=TRUE, ...)
```

**Arguments**

- `x` numeric vector containing the read counts.
- `plot` If `TRUE` (the default) then the plot with the ECDF function for the counts and the three different Poisson-Tweedie distributions is produced, otherwise no graphical output is given and this only makes sense if one is interested in the returned value (see value section below).
- `...` Further arguments to be passed to the plot function.

**Details**

This function serves the purpose of comparing a empirical distribution of counts with three Poisson-Tweedie distributions arising from estimating mean, dispersion and setting $a = 1$ for comparing against a Poisson, $a = 0$ for comparing against a negative binomial and estimating the shape parameter $a$ from data too. The legend shows the values of the $a$ parameter and the P-value of the likelihood ratio test on whether the expression profile follows a negative binomial distribution ($H_0 : a = 0$).

**Value**

List with the following components:

- `a` shape parameter estimated from the input data $x$.
- `p.value` P-value for the test that the data follows a negative binomial distribution, i.e., $H_0 : a = 0$.

xx

The Poisson-Tweedie family of distributions

Description

Density function and random generation for the Poisson-Tweedie family of distributions.

Usage

dPT(x, mu, D, a, tol = 1e-15)
rPT(n, mu, D, a, max = 10*sqrt(mu*D), tol = 1e-4)

Arguments

- x: an object of class 'mlePT' or a non-negative vector containing the integers in which the distribution should be evaluated.
- mu: numeric positive scalar giving the mean of the distribution.
- D: numeric positive scalar giving the dispersion of the distribution.
- a: numeric scalar smaller than 1 giving the shape parameter of the distribution.
- tol: numeric scalar giving the tolerance.
- n: integer scalar giving number of random values to return.
- max: numeric scalar containing the maximum number of counts to be used in the sampling process.

Value

If 'x' is of class 'mlePT', 'dPT' will return the Poisson-Tweedie distribution with parameters equal to the ones estimated by 'mlePoissonTweedie' evaluated on the data that was used to estimate the parameters. If 'x' is a numeric vector, 'dPT' will return the density of the specified Poisson-Tweedie distribution evaluated on 'x'.

'rPT' generates random deviates.

References

filterCounts

Count data filtering

Description
Filter count data to remove lowly expressed genes.

Usage
filterCounts(counts, cpm.cutoff=0.5, n.samples.cutoff=2, mean.cpm.cutoff=0, lib.sizes=NULL)

Arguments
counts numeric data.frame or matrix containing the count data.
cpm.cutoff expression level cutoff defined as the minimum number of counts per million. By default this is set to 0.5 counts per million.
n.samples.cutoff minimum number of samples where a gene should meet the counts per million cutoff (cpm.cutoff) in order to be kept as part of the count data matrix. When n.samples.cutoff is a number between 0 and 1, then it is interpreted as the fraction of samples that should meet the counts per million cutoff (cpm.cutoff).
mean.cpm.cutoff minimum mean of counts per million cutoff that a gene should meet in order to be kept. When the value of this argument is larger than 0 then it overrules the other arguments cpm.cutoff and n.samples.cutoff.
lib.sizes vector of the total number of reads to be considered per sample/library. If lib.sizes=NULL (default) then these quantities are estimated as the column sums in the input matrix of counts.

Details
This function removes genes with very low expression level defined in terms of a minimum number of counts per million occurring in a minimum number of samples. Such a policy was described by Davis McCarthy in a message at the bioc-sig-sequencing mailing list. By default, this function keeps genes that are expressed at a level of 0.5 counts per million or greater in at least two samples. Alternatively, one can use the mean.cpm.cutoff to set a minimum mean expression level through all the samples.

 glmPT

Fit Poisson-Tweedie generalized linear model.

Description

'glmPT' is used to fit generalized linear models for the Poisson-Tweedie family of distributions.

Usage

tweeDEglm(formula, counts, data, mc.cores = 1, a = NULL, offset = NULL, ...)
glmPT(formula, data, offset = NULL, a = NULL, ...)

Arguments

formula an object of class 'formula': a symbolic description of the model to be fitted.
counts Matrix or data.frame of counts for the 'tweeDEglm'.
data an optional data frame, list or environment containing the variables in the model. If not found in 'data', the variables are taken from ’environment(formula)’, typically the environment from which ’glm’ is called.
m.cores number of cpu cores to be used. This option is only available when the ’multi-core’ package is installed and loaded first. In such a case, if the default value of ’mc.cores=1’ is not changed, all available cores will be used.
offset this can be used to specify an _a priori_ known component to be included in the linear predictor during fitting.
a numeric vector (for `tweeDEglm`) or numeric scalar (for `glmPT`) smaller than 1. If specified the PT shape parameter will be fixed. For `tweeDEglm`, if the provided `a` is a scalar this value will be used for all rows of `counts` (genes).
...
additional arguments to be passed to the `optim` `control` options.

Value
An object of class `glmPT` containing the following information:
call the matched call.
contrasts (where relevant) the contrasts used.
convergence A character string giving any additional information returned by the optimizer, or `’NULL’`.
counts A two-element integer vector giving the number of calls to ‘fn’ and ‘gr’ respec-
tively. This excludes those calls needed to compute the Hessian, if requested,
and any calls to ‘fn’ to compute a finite-difference approximation to the gradient.
df Number of estimated parameters.
fitted.values The fitted mean values, obtained by transforming the linear predictors by the
inverse of the link function.
hessian A symmetric matrix giving an estimate of the Hessian at the solution found.
message A character string giving any additional information returned by the optimizer,
or `’NULL’`.
ncov An integer giving the number of variables in the model.
par A vector giving the estimated parameters.
residuals The residuals in the final iteration of the IWLS fit.
se A vector giving the standard error of the estimated parameters.
value Value of the log-likelihood of the model in the last iteration.
... Further arguments to be passed to the `glm.fit` function.

Author(s)
Mikel Esnaola <mesnaola@creal.cat>

Examples
```r
counts <- matrix(rPT(n = 1000, a = 0.5, mu = 10, D = 5), ncol = 40)
g <- factor(rep(c(0,1), 20))
mod1 <- glmPT(counts[1,]-g)
mod1
summary(mod1)
anova(mod1)

mod2 <- tweeDEglm(~ g, counts)
mod2
```
**gofTest**  
*Test the goodness of fit of every row in a matrix of counts*

### Description

Function to test the goodness of fit of every row in a matrix of counts.

### Usage

```r
gofTest(counts, a = 0, mc.cores = 1)
```

### Arguments

- **counts**: matrix of counts
- **a**: numeric scalar smaller than 1. The function will test whether the shape parameter is equal to the introduced ‘a’ (default is 0).
- **mc.cores**: number of cpu cores to be used. This option is only available when the ‘multicore’ package is installed and loaded first. In such a case, if the default value of mc.cores=1 is not changed, all available cores will be used.

### Details

By default $a = 0$, and therefore the function tests for every row of the input matrix of counts whether the count data follows a Negative-Binomial distribution. In this case, a Likelihood Ratio Test is performed. When the given value for ‘a’ is different from 0, a Wald test is performed. This function calls `testShapePT`.

### Value

A vector of statistics that follows a $\chi^2$ distribution with one degree of freedom under the null hypothesis.

### References

### See Also

`testShapePT`
Methods for objects of class ‘mlePT’

Examples

```r
## Generate a random matrix of counts
counts <- matrix(rPT(n=2000, a=0.5, mu=10, D=5), nrow=20)

## Perform the goodness-of-fit tests for every row in the matrix
chi2gof <- gofTest(counts)

## Calculate and sort the corresponding P-values for the null hypothesis that counts follow a negative binomial distribution
sort(pchisq(chi2gof, df=1, lower.tail=FALSE))
```

Methods for objects of class ‘mlePT’

Description

print, extract loglikelihood or compute confidence interval for an object of class ‘mlePT’.

Usage

```r
## S3 method for class 'mlePT'
print(x, digits = 3, ...)
## S3 method for class 'mlePT'
logLik(object, ...)
## S3 method for class 'mlePT'
confint(object, parm, level = 0.95, ...)
```

Arguments

- `x`: object of class ‘mlePT’.
- `object`: object of class ‘mlePT’.
- `digits`: integer scalar giving the number of digits to be rounded the solution.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required (default is 0.95).
- `...`: additional arguments.

Value

- `logLik` returns the loglikelihood of the selected model.
- `confint` returns a matrix (or vector) with columns giving lower and upper confidence limits for each parameter.

confint(mleSeizure)

mlePoissonTweedie

Maximum likelihood estimation of the Poisson-Tweedie parameters

Description

Maximum likelihood estimation of the Poisson-Tweedie parameters using L-BFGS-B quasi-Newton
method.

Usage

mlePoissonTweedie(x, a, D.ini, a.ini, maxit = 100, loglik=TRUE,
maxCount=20000, w = NULL, ...)
getParam(object)

Arguments

x     numeric vector containing the read counts.
a     numeric scalar smaller than 1, if specified the PT shape parameter will be fixed.
D.ini numeric positive scalar giving the initial value for the dispersion.
a.ini numeric scalar smaller than 1 giving the initial value for the shape parameter
(ignored if 'a' is specified).
maxit numeric scalar providing the maximum number of 'L-BFGS-B' iterations to be
performed (default is '100').
loglik is log-likelihood computed? The default is TRUE
object an object of class 'mlePT'.
maxCount if max(x) > maxCount, then moment method is used to estimate model parame-
ters to reduce computation time. The default is 20000.
w     vector of weights with length equal to the length of 'x'.
...   additional arguments to be passed to the 'optim' 'control' options.
Details

The L-BFGS-B quasi-Newton method is used to calculate iteratively the maximum likelihood estimates of the three Poisson-Tweedie parameters. If 'a' argument is specified, this parameter will be fixed and the method will only estimate the other two.

Value

An object of class 'mlePT' containing the following information:

- **par**: numeric vector giving the estimated mean ('mu'), dispersion ('D') and shape parameter 'a'.
- **se**: numeric vector containing the standard errors of the estimated parameters 'mu', 'D' and 'a'.
- **loglik**: numeric scalar providing the value of the loglikelihood for the estimated parameters.
- **iter**: numeric scalar giving the number of performed iterations.
- **paramZhu**: numeric vector giving the values of the estimated parameters in the Zhu parameterization 'a', 'b' and 'c'.
- **paramHou**: numeric vector giving the values of the estimated parameters in the Hougaard parameterization 'alpha', 'delta' and 'theta'.
- **skewness**: numeric scalar providing the estimate of the skewness given the estimated parameters.
- **x**: numeric vector containing the count data introduced as the 'x' argument by the user.
- **convergence**: A character string giving any additional information returned by the optimizer, or 'NULL'.

normalizeCounts

counts
group
method
common.disp
prior.df
annot
lib.sizes
verbose

description
normalize count data to remove systematic technical effects.

usage
normalizeCounts(counts, group=rep.int(1,ncol(counts)), method=c("TMM", "cqn"),
common.disp = FALSE, prior.df=8, annot=NULL, lib.sizes=NULL, verbose=TRUE)

arguments
counts numeric data.frame or matrix containing the count data.
group vector giving the experimental group/condition for each sample/library. This
argument is only relevant when method="cqn".
method specific method to use in order to normalize the input matrix of counts. By de-
default this is set to TMM (Robinson and Oshlack, 2010) using the implementation
available in the edgeR package. The other option is cqn (Hansen, Irizarry and
Wu, 2012).
common.disp logical indicating whether a common or tagwise (default) dispersions should be
estimated and employed when adjusting counts. This argument is only relevant
when method="TMM".
prior.df argument provided to the call of estimateTagwiseDisp which defines the prior
degrees of freedom. It is used in calculating 'prior.n' which, in turn, defines
the amount of shrinkage of the estimated tagwise dispersions to the common
one. By default prior.df=8 thus assumming no shrinkage toward that common
dispersion. This argument is not used if common.disp=TRUE. This argument is
only relevant when method="TMM".
annot matrix or data frame with row names matching at least part of the row names
in the counts input matrix, containing feature/tag/gene lengths in bp on its first
column, and a second covariate, such as G+C content, on its second column.
These two pieces of information are provided to arguments lengths and x when
calling cqn. This argument is only relevant when method="TMM".
lib.sizes vector of the total number of reads to be considered per sample/library. If
lib.sizes=NULL (default) then these quantities are estimated as the column
sums in the input matrix of counts.
verbose logical indicating whether progress should be reported.

details
This function encapsulates calls to RNA-seq normalization procedures available in the edgeR
and cqn packages in order to try to remove systematic technical effects from raw counts. By default, the
TMM method described in Robinson and Oshlack (2010) is employed to calculate normalization
factors which are applied to estimate effective library sizes, then common and tagwise (only when

the argument common.disp=TRUE) dispersions are calculated (Robinson and Smyth, Bioinformatics 2007) and finally counts are adjusted so that library sizes are approximately equal for the given dispersion values (Robinson and Smyth, Biostatistics 2008). Setting the argument method="cqn", conditional quantile normalization (Hansen, Irizarry and Wu, 2012) is applied which aims at adjusting for tag/feature/gene length and other covariate such as G+C content. This information should be provided through the annot argument. This procedure calculates, for every gene and every sample, an offset to apply to the log2 reads per million (RPM) and the function normalizeCounts() adds this offset to the the log2 RPM values calculated from the input count data matrix, unlogs them and rolls back these normalized RPM values into integer counts. Details on these two normalization procedures are given in the documentation of the edgeR and cqn Bioconductor packages.

Value

A matrix of normalized counts.

Author(s)

J.R. Gonzalez and R. Castelo

colSums(normCounts)
normCounts[1:5, 1:5]
**qqchisq**  
**Chi-square quantile-quantile plot**

**Description**

Make a chi-square quantile-quantile plot.

**Usage**

```r
qqchisq(stat, df=1, normal=FALSE, rangeExpected=FALSE,
        obsQuantiles=c(0.50, 0.75, 0.95), ylim = NULL, ...)
```

**Arguments**

- `stat` vector of $\chi^2$ statistics.
- `df` degrees of freedom of `stat`.
- `normal` logical; set to `TRUE` if the $\chi^2$ statistics in `stat` should be transform into normal z-scores in order to improve the display of lower quantiles. For this purpose, this function uses the `zscoreGamma` function from the limma package. Default is set to `FALSE`.
- `rangeExpected` logical; set to `TRUE` if the displayed range of the observed $\chi^2$ statistics is restricted to the range of their expected values. Default is set to `FALSE`.
- `obsQuantiles` observed quantiles to indicate by horizontal dash lines. By default, these are set to 50%, 75% and 95%.
- `ylim` they y limits of the plot. If 'NULL' (default), these will be obtained from the data.
- `...` further arguments to pass to the `plot` function.

**Details**

The main purpose of this function in the `tweeDEseq` package is to provide means to assess the goodness of fit of count data to the negative binomial distribution. The main input argument `stats` should be the output of `goffest`.

**Value**

it returns invisibly a list with two components `x` and `y` corresponding to the coordinates of the plotted statistics.

## End(Not run)
```

seizure

Epileptic seizure counts

Description

Data on seizure counts for 59 epileptics.

Usage

data(seizure)

Format

A data frame with 236 observations on the following 6 variables.

- `id` a numeric vector, identification number for each patient
- `count` a numeric vector, seizure counts
- `visit` a numeric vector, visit number
- `trx` a numeric vector, treatment: progabide (1) or placebo (0)
- `baseline` a numeric vector, baseline 8 week seizure count
- `age` a numeric vector, age of patient

Details

The data are from a placebo-controlled clinical trial of 59 epileptics. Patients with partial seizures were enrolled in a randomized clinical trial of the anti-epileptic drug, progabide. Participants in the study were randomized to either progabide or a placebo, as an adjuvant to the standard anti-epileptic chemotherapy. Progabide is an anti-epileptic drug whose primary mechanism of action is to enhance gamma-aminobutyric acid (GABA) content; GABA is the primary inhibitory neurotransmitter in the brain. Prior to receiving treatment, baseline data on the number of epileptic seizures during the preceding 8-week interval were recorded. Counts of epileptic seizures during 2-week intervals before each of four successive post-randomization clinic visits were recorded.

testShapePT

Test shape parameter of PT

Description

Function to test whether the shape parameter is equal to a given value.

Usage

testShapePT(x, a = 0)

Arguments

x object of class ’mlePT’.
a numeric scalar smaller than 1. The function will test whether the shape param-
eter is equal to the introduced ’a’ (default is 0).

Details

By default a = 0, and therefore the function tests whether the count data follows a Negative-Binomial distribution or not. In this case, a Likelihood Ratio Test is performed. When the given value for ’a’ is different from 0, a Wald test is performed.

If a = 1, the function tests whether the count data follows a Poisson distribution or not.
If $a = 0.5$, the function tests whether the count data follows a Poisson-inverse Gaussian distribution or not.

If $a = -1$, the function tests whether the count data follows a Polya-Aeppli distribution or not.

**Value**
numeric p-value of the test.

**tweeDE**  
*Score test for differences between two Poisson-Tweedie groups*

**Description**

Carry out a score test for differences between two Poisson-Tweedie groups.

**Usage**

tweeDE(object, group, mc.cores = 1, pair = NULL, a = NULL, 
      saveModel = FALSE, a = NULL, log = FALSE, 
      sort.by="pval", log2fc.cutoff=0, pval.adjust.cutoff=1, print=TRUE, ...)

```r
## S3 method for class 'tweeDE'
print(x, n=6L, sort.by="pval", 
      log2fc.cutoff=0, pval.adjust.cutoff=1, print=TRUE, ...)
```
## S3 method for class 'tweeDE'
MAplot(x, log2fc.cutoff=0, highlight=NULL, ...)

## S3 method for class 'tweeDE'
Vplot(x, log2fc.cutoff=0, pval.adjust.cutoff=1, highlight=NULL, ylab=expression(paste(-log[10], " Raw P-value")), ...)

### Arguments

- **object**: a data.frame or a matrix of RNA-seq counts.
- **group**: vector giving the experimental group/condition for each sample/library.
- **mc.cores**: number of cpu cores to be used. This option is only available when the 'multicore' package is installed and loaded first. In such a case, if the default value of `mc.cores=1` is not changed, all available cores will be used.
- **pair**: vector of two elements containing the representants of each of the two groups (default is 'NULL').
- **a**: for 'tweeDE' function, numerical vector with values strictly less than 1. It allows to fix the shape parameter 'a' during differential expression tests for each of the genes (rows of 'object'). for 'testPoissonTweedie' function, numeral value strictly less than 1 which fixes the shape parameter 'a' for the test.
- **n**: maximum number of genes printed.
- **sort.by**: character string, indicating whether genes should be ranked by their P-value (pval), which is the default setting, or by absolute log2 fold-change (log2fc).
- **log2fc.cutoff**: cutoff on the minimum value of the log2 fold change.
- **pval.adjust.cutoff**: cutoff on the maximum adjusted P-value (FDR).
- **print**: logical; it indicates whether the output should be printed on the terminal.
- **highlight**: list of arguments to the points() plotting function in order to highlight genes in the MA or volcano plots. A component called genes is expected to have the identifiers of the genes to be highlighted.
- **ylab**: label on the y-axis of the volcano plot set by default to -log10 of the raw P-value which is what this plot displays on that axis.
- **x**: object returned by the function tweeDE in the case of print and vector of count data in the case of testPoissonTweedie.
- **saveModel**: logical indicating whether the results of fitting the model should be saved or not (default is 'FALSE').
- **log**: logical (default is FALSE). If FALSE, the tested Null Hypothesis states that the difference between the means is 0 while, if TRUE, it states that the quotient between the logarithm of means is equal to 1. For this last case, the standard error is computed using the Delta Method.
- **...**: additional arguments.

### Details

'testPoissonTweedie' performs the test for a vector of counts.

'tweeDE' performs the test for a whole 'data.frame'. The P-values are then corrected using the Benjamini and Hochberg method.
tweeDExact

Exact test for differences between two Poisson-Tweedie groups

Description

Carry out an exact test for differences between two Poisson-Tweedie populations.

Usage

\texttt{tweeDE\textbackslash{}Exact(counts, group, tol = 1e-15, mc\textunderscore{}cores = 1)}
\texttt{exactTestPT(counts, group, tol = 1e-15, threshold = 150e3)}

Arguments

\begin{itemize}
  \item \texttt{counts} The RNA-seq counts. An object of type \texttt{matrix} or \texttt{data.frame} for \texttt{tweeDE\textbackslash{}Exact}, or an object of type \texttt{vector} for \texttt{exactTest}.
  \item \texttt{group} vector giving the experimental group/condition for each sample/library.
  \item \texttt{tol} Tolerance for the Poisson-Tweedie probability computations. The probabilities under the \texttt{tol} value will automatically considered as 0.
\end{itemize}

Value

\begin{itemize}
  \item \texttt{testPoissonTweedie} returns a list with:
    \begin{itemize}
      \item \texttt{mean}: means for each group
      \item \texttt{pvalue}: p-value for the test
    \end{itemize}
  \item \texttt{tweeDE} returns a \texttt{data.frame} with columns
    \begin{itemize}
      \item \texttt{overallMean}: overall mean counts
      \item \texttt{meanA}: mean counts of the first group
      \item \texttt{meanB}: mean counts of the second group
      \item \texttt{log2fc}: logarithm (base 2) of the fold-change (second group vs. first group)
      \item \texttt{pval}: p-value for the test
      \item \texttt{pval.adjust}: adjusted p-value using Benjamini-Hochberg method
    \end{itemize}
\end{itemize}

\texttt{normalizeCounts mlePoissonTweedie}

Examples

\begin{verbatim}
# Generate a random matrix of counts
counts <- matrix(rPT(n = 1000, a = 0.5, mu = 10, D = 5), ncol = 40)

# Test for differences between the two groups
tweeDE(counts, group = rep(c(1,2),20))
\end{verbatim}
threshold: an integer (default is 50e3). If the sum of all counts in a certain gene exceeds this value, `testPoissonTweedie` will be called instead of `exactTest`. Larger values will result in a longer computing time.

mc.cores: number of CPU cores to be used. This option is only available when the `multicore` package is installed and loaded first. In such a case, if the default value of `mc.cores=1` is not changed, all available cores will be used.

Details

`exactTest` performs the exact test for a vector of counts.

`tweeDExact` performs the test for a whole `data.frame`. The P-values are then corrected using the Benjamini and Hochberg method.

Value

`exactTest` returns the p-value resulting from the exact test between two different Poisson-Tweedie populations, as well as the method that was used to compute it.

`tweeDExact` returns a `data.frame`. Each row corresponds to a gene and it contains the following information:
- In the first columns the mean of counts in each of the subgroups.
- In the third column the p-value of the test for differential expression between the two subgroups.
- In the fourth column the p-value corrected for multiple comparisons using the Benjamini-Hochberg FDR procedure.
- In the last (fifth) column the method that was used to compute the p-value.
